The representative of Messrs. Aldis, owing to a series of railway mishaps, was unable to reach the Royal Photographic Society in time to read the paper by his firm. The text of the paper is as follows:—

One of the most interesting, and from an industrial point of view one of the most healthy, effects of war on industry is the way in which it stimulates rapid adaptation to quite new conditions of manufacture. In the early stages of the war the firm of Aldis Brothers found itself suddenly forced to concentrate entirely on the production of telescopic rifle sights for snipers. This was due to the fact that our firm was one of the first to submit a model to the War Office which entirely satisfied all their requirements. The demand was so great at the time that once the firm's capacity had been proved as regards optical design the Ministry of Munitions made it their business to see that all the resources of the firm were concentrated on working up the largest possible output of that one optical munition. Thus, at the very outset of the war the firm found themselves wholly abandoning photographic lenses. One factor influencing the situation, of course, was that the only pre-war Aldis series of lenses of sufficient rapidity for aircraft photography had not at that time been established in

long enough focal lengths to be really suitable for the work.

The demand for the Aldis telescopic rifle sight was fairly at its zenith when there was a great scare at the front due to the Germans jamming our wireless messages from aeroplanes. An official at the War Office had read a pamphlet written by A. C. W. Aldis on "Electric Projectors," and in consequence the firm was asked to report on the possibility of establishing a portable daylight signal lamp for use to and from aeroplanes, so as to provide a second string to wireless.

The firm attacked this problem with such zeal that in the end the Aldis daylight signal lamp for aeroplanes was designed and submitted, and the success of this invention seemed to throw further and further into the background the possibility of our ever touching photographic lenses during the war.

It then became the understood thing for the aircraft people to take all electric projection problems to Aldis Brothers, and a great variety of landing lights and portable searchlights were designed for use on aircraft. A great deal of this work

was design pure and simple, the firm having nothing to do with manufacture as soon as models had been passed as satisfactory.

In 1916 the firm submitted the first Aldis unit sight for aiming machine-guns on aeroplanes, and the enormous success which this ultimately attained soon put the Aldis telescopic rifle sight in the shade; in fact, early in 1917 we were again in the unfortunate position of having produced an invention which it was quite impossible for us to produce in sufficient quantities. We were obliged to organise production on a large scale in two other factories, and by this, and by making considerable extensions to our own works as well, the demand was ultimately met to the entire satisfaction of the Ministry of Munitions.

During all this time the ever-increasing popularity of the Aldis daylight signal lamp taxed the firm's resources to the utmost. Manufacture was established in other works of everything except the very special optical sight, which we alone could produce. Everything we had designed was wanted in quantities not only larger than we could produce, but apparently larger than we could get produced.

It will be therefore readily understood that when a representative of the Photographic Section of the Royal Air Force called at Aldis Brothers' towards the end of 1917 and requested us to take up the manufacture of large photographic lenses, he was received not altogether with open arms. The firm was working up to the limit of its then capacity, and in addition had mortgaged its extensions then being erected, to increase the deliveries of unit sights in response to the continual demands made upon it. However, the R.A.F. representative, after much exercise of his considerable powers of persuasion, was not at all pleased to receive a blank *non possumus*.

The firm consented to take the photographic lens up only after continual repetition of the following sort of argument: "Mr. Aldis, you were manufacturers of photographic lenses before the war; photographic lenses are wanted now in ever-increasing quantities, and the other sources of supply are working at maximum capacity; you were manufacturers of photographic lenses before the war; you must and shall supply us with photographic lenses now."

At last we agreed to consider the production of aircraft anastigmats, whereupon the representative of the R.A.F. produced a captured Zeiss lens, of aperture $f/4.8$ and 20-in. focal length. He said: "This is the sort of thing we want, but there are two difficulties about copying it exactly: one is that these precise types of glass are not in the list of British glass-makers, and have to be obtained from France, and the other is that neither in this country nor in France are slabs of this size and quality to be obtained in sufficient quantity to meet the demand. We are therefore prepared to take a smaller aperture lens, say $f/5.6$, of the same focal length."

Aldis Brothers' reply was first to get into touch with Messrs. Chance in the matter and review the question as to the supply of large circular slabs of highest quality glass supplied in considerable numbers. They reported that they were able to supply a large quantity of discs large enough for the $f/5.6$ lens, provided we took glass of their then established types, also later on they could supply smaller quantities of discs for much larger lenses. This glass was quite as good as the German glass in the Zeiss lens, but it was very distinctly different. This entirely precluded any question of merely copying the captured lens, which line of attack incidentally Aldis Brothers were fully determined to have nothing whatever to do with. The firm then applied to the R.A.F. authorities for permission to design and manufacture the best possible photographic lens of the focus and aperture required, and covering the specified plate, but the glass to be of British make. This permission the R.A.F. granted, albeit with mis-

giving on the part of the higher authorities, who still had grave fears that after all the German-designed article made of French glass could not help being superior to anything of purely British origin.

The lens was calculated, trial models were made, and finally the first lens was sent off in trial mount on New Year's Eve, 1917. We are able to produce this trial lens. The Photo-Section was enthusiastic about it, and informed us that, over the plate we had been asked to cover, it was proved to be superior to the German article. Contracts were placed for the lens, and supplies of the purely British article were forthcoming in considerable quantities. The other lens shown herewith is one which has done good work, but has received a bullet in the middle. The glasses are undamaged, and it will take an excellent photograph, but the centring has been slightly impaired.

Bearing in mind the promise of Messrs. Chance to supply slabs of much larger sizes, two fresh designs were put in hand. One of these was a 36-in. $f/6$ to cover a 10 ins. by 8 ins. plate with critical definition. This huge lens we are enabled to show by the courtesy of the R.A.F. authorities and Mr. C. Houghton. One of the first duties it was destined for was the examination of Zeebrugge, where the anti-aircraft organisation was troublesomely effective, and photography was done from such heights as three miles.

The second lens put in hand was one of 20 in. focus working at $f/4$. This was also made of entirely English glass, though another type of flint was used. It was designed to cover a 10 by 8 plate, as in the meantime the British standard plate had been increased to this size to come into line with the Americans and other Allies. We are able to show herewith the trial lens, which was very favourably reported on. At the same time the standard 20-in. $f/5.6$ was also modified for use with the 10 by 8 plate.

All these lenses are of the triplet type. This type of lens is one which has a very great deal to be said for it, though, of course, every type of lens manufactured has its strong points. These very long focus aircraft photographic lenses are naturally used on quite a narrow angle. They also tend to be quite long in the barrel, partly for this reason, and as a consequence the curves are shallow compared with the ordinary terrestrial photographic lens. As a result, when the corrections of the lens have been worked out fully, the quality of the definition is amazingly good compared with the terrestrial lens, in spite of the fact that the image is on so much larger a scale. A series of test charts which the R.A.F. authorities have very kindly permitted us to show to-night will enable anyone to see at a glance the microscopic definition which the Flying Corps demand and the lenses afford.

It was found in practice that trouble, when it arose in testing these lenses, was due (after the initial stages) not to deficiencies on the part of the workmen—only old and experienced hands worked on these lenses, and seemed to succeed very well in turning out the very best work—nor to deficiencies in design or in the construction of the metal work, but in those minute variations in the refractive index and homogeneity generally which are the more liable to occur the larger the lens. This was in spite of the fact that Messrs. Chance instituted a rigorous testing of every single slab supplied by means of the interferometer, and that the quality of these discs was undoubtedly maintained very high.

The telephoto type of lens was given very serious consideration, but abandoned. This type of lens for long focus aerial work has undoubtedly a great deal to be said for it, and it has found particular favour with certain of our Allies. It permits of a short camera, and this with a long focus lens in an aeroplane is really very important, as otherwise the lens or camera or both may project from the fuselage and slow the aeroplane; also the lens is the better for being well

shielded. The angle of view included is, generally speaking, within the limits that the type of lens is capable of, though it often approaches those limits.

The reasons Aldis Brothers had for not adopting the telephoto type were practical and cogent. First, it is very subject to pincushion distortion, and this, which does no harm when photographing sporting events and the like, is a serious handicap for map work. Secondly, it is, compared with the triplet, *expensive in glass*. This is very bad in war-time, because the shortage of raw material always tended to be more serious than the shortage of skilled labour. Clearly it can hardly consist of less than four glasses, and may include five or more, and these glasses are rather thick. Admitted that those forming the back negative lens are smaller than the others, yet it is undeniable that, compared with the simple triplet, they do demand a lot of glass. It will be remembered that when the firm undertook the manufacture of large photographic lenses the heavy demand for these was accompanied by serious misgivings as to the quantity of first-class optical glass in large slabs which could be made available.

Furthermore, it is distinctly doubtful whether the telephoto lens at its very best will ever quite attain to the high standard of definition afforded by the triplet lens at its very best. It is, however, to be expected that when glass supplies become more normal and designs of such lenses progress, their use will be relatively on a more extended scale than was possible during the war.

It may be of interest to mention the time taken to calculate a large photographic lens. During the purely calculating stages two computers working side by side under supervision of the head designer may work steadily on for three months before models are put in hand. When models begin to be made the number of these may be as many as eight, if the lens is of new type, or only one if we are working on lines in which we have much experience. The time of making a model, of examining it, and of carrying out the calculations which ensue before the next model is put in hand is about three weeks. When the lens has been got right it will take a considerable time to prepare all the spherical tools for the working of the different surfaces.

It may be interesting to mention that a certain amount of trouble arose with these lenses owing to the fact that their focal length was actually comparable with any terrestrial distance which was available.

Ordinary photographic lenses are tested with an "artificial star" at a distance of between 60 and 70 ft.: this for the ordinary camera lens is *further off* than the point usually described as "infinity," but it is quite a different matter with a lens of 36 in. focus. This with a 60 ft. star is racked out beyond its infinity focus very nearly 2 ins. The furthest sharp-cut terrestrial object available was a flagstaff half a mile away, which meant racking past infinity something like .04 in.—quite an appreciable distance at $f/5.6$ with microscopic definition. As regards celestial objects, these are only seen

at night, and to use a real star would be quite possible, but hardly compatible with factory conditions.

The lenses are mounted in a special form of mount to go into the standard aeroplane cameras. They screw into a standard flange in which the mount can be locked in any position within the limits of an inch or more. This is for focussing—that is to say, to take up slight differences in focal length, due as much as anything to slight differences between the optical constants of one slab and another. Variations of $\frac{1}{4}$ in. either way in a 20-in. lens do occur, and are not readily preventable in quantity production.

The mounting is such that glasses cannot readily be taken out. Aeroplanes do come to grief, from quite a lot of possible causes, and valuable stuff can be salvaged off them. The souvenir craze is quite bad enough to cause a Tommy to march off with the front glass only of a valuable anastigmat in his pocket—a criminally wasteful proceeding when the anastigmat is undamaged. Even when one glass is broken or the lens mount smashed up it is quite feasible to have these replaced and made up with the undamaged elements into a new lens.

The mount, therefore, is designed not to be readily taken to pieces without tools, and yet so that with simple tools and the requisite knowledge every surface of every glass can be cleaned without removing the mount body from the camera or disturbing the focus adjustment.

No iris diaphragm is fitted to these large lenses. The definition is so good that stopping down does not improve it, and anything in hand in the matter of plate speed is at once taken up by using a deeper light filter. As everything is at infinity there is no "depth of focus" problem.

As regards weight, it may be interesting to mention that the 20-in. $f/5.6$ lens, including flange, but without screen and screen cell, weighs 5½ lbs., of which the lenses account for just over 1½ lbs. Corresponding figures for the 20-in. $f/4$ are 10 lbs. and 4 lbs., and for the 36-in. $f/6$ are 16¾ lbs. and 7 lbs.

For these long focus lenses and great heights of flying, light-filters are indispensable to cut out the effect of the selective absorption of the atmosphere. The nature of the dyestuffs in these filters is a study in itself, but as Messrs. Wratten and Wainwright, in their book, "Orthochromatic Filters," point out, the *optical* properties of filters need careful attention. A little thought will show that except for their being flat rather than spherical, the quality of the optical work and the homogeneity of the glass in the filters must be maintained to exactly the same standard as in the glasses of the anastigmat itself. In point of fact, the two flats between which the filters are cemented are very carefully made, and are distinctly expensive. Such a filter as the one for the 36-in. $f/6$, for instance, consists of two glasses each 6⅝ in. diameter and $\frac{3}{8}$ in. thick, each weighing $\frac{1}{2}$ lb.

The filters go into cells fitted on to the front of the lens. These slip over the mount and are retained by a bayonet fitting, standardised so that any mounted filter will go straight away on to any lens of corresponding size.

CONCERNING TONE VALUES.

[Tonality as the property of a photograph, and particularly of a portrait photograph, is perhaps the quality in respect of which the constant progress of photographic art will exhibit its chief development. Photographers within the last decade or so have come to a much fuller understanding of the amenities which a portrait should display in the matter of composition. But after all composition is only one of the things which contributes to the making of a work of art, and therefore we quote from our contemporary, the "Photographic Journal of America" some notes which very usefully lay emphasis on the laws, so far as they can be formulated, which relate to this all-important matter of "tone."—Eds. "B.J."]

TONE, in an art sense, should not be construed by the professional photographer to mean colour. We have for years past used the word in defining the colour of our prints, such as the blue, purple, olive, black, or sepia tone, etc., but this relates to the results pro-

duced by our chemicals. Artists frequently use the word in the same sense as we do, enlarging its scope by various other expressions, such as "cool," "warm," or "rich" tones; but when they so express themselves it is evident to those with whom they

converse that they refer either to the colour tone which prevails throughout, or to the strength or depth of this colour.

Now, while admitting that the word "tone" is thus used by artists, as exemplifying a principle in pictorial art, it is understood by them to mean at least two other things.

1. Atmosphere Tone.

The obtaining of an effect over the whole picture, similar to what would be produced if we were to interpose a transparent and meshless veil of harmonious tint before the picture, through which the light would pass as through an atmosphere. It may very easily be imagined that this would result in bringing all parts of the picture into harmony, by placing in their proper planes of attractiveness, etc., all the colours, lights and shades, perspective, and the various values. This we will designate as "atmosphere tone."

2. Light Tone.

Tone is also understood as meaning the gradations of the light falling upon the objects painted or photographed in various degrees of intensity; the gradations of chiaroscuro, or light and shade. This we will call "light tone."

We will comment but little upon "colour tone," most familiar to photographers by long usage, except to state the well-known fact that many false tones are apparent at times in our printed-out papers, where the faces, hands, and other masses of white are not of the same colour or tone as the shadows, etc. Since our various paper demonstrators have for years, at our conventions and in our studios, touched upon a solution of this matter, it is unnecessary for the writer to go further into a subject so well understood by us all.

The "tone" produced, illustrated by the interposition of a veil, as descriptive of a certain effect which we wished to describe, and the "light and shade tone" afterward mentioned, will form the subject of our further remarks on the subject of tone, as more nearly coming within the exact meaning of the term in a pictorial sense. We shall refer to them irrespective of any further classification or intent of separation.

"Light tones" may be further defined as meaning the harmonious blending, by gradation, of all the lights into the darks, in their proper degree of shade. In other words, the gradation of the multitude of little lights and darks to their adjacent parts; of the larger masses of various degrees of light and dark to each other, and then, in turn, of every part to the whole. The result as a whole may be light, medium, or low in key, and yet be in tone.

Tonality.

Unity of tone by gradation may be present in certain parts of the picture and absent elsewhere. When it envelops the whole picture like an atmosphere (which under certain conditions is easily and charmingly produced in a landscape), then such a picture is complete in tone in all its parts: its "tonality is good."

Improved tonality in portraiture may be obtained by placing the subject away from strong light, as when working for colour values. This causes the light and shade that fall upon the sitter, and other parts of the composition, to easily fall into any degree of gradation that the pictorialist may desire: i.e., slight changes will often be found necessary to keep these gradations in harmony. For instance, he hardly expects that the chair as first placed is exactly where he will wish it in the final composition. He must judge the effect of colour values as well as the ultimate pitch of the key in tone.

Pictorial workers often describe this placing of the subjects in a suitable location in the room as "bringing them in tone," "arranging the composition in tone," "placing them where they will be in tone," etc.

The distinctions between various principles are sometimes very slight, especially so in monochrome work, and all effect toward the attainment of one materially aids the successful accomplishment of others.

Tone Improperly Rendered.

Pictures may be out of tone in some of their parts, although in good order elsewhere, simply because the parts do not pull together or harmonise with the rest. It may be that certain places are too white, such as the face, hands, collar, cuffs, etc. These, on account of their startling appearance (due to "forcing" forward by too

strong lighting or other causes), appear to "jump at you." Remedy: In lighting the composition throw more shade on these places.

It may be that other parts, not quite so prominent, perhaps, but in greater number, are at fault. These impress you as disturbing the harmony of the composition by their distracting assertiveness. Remedy: Throw more shade on these parts. If in background, place it farther away from the direct light. If in accessories, remove them from the picture if possible.

In the earlier papers of this series we have frequently referred to the importance of making various elements that enter into the picture take their proper positions in attractiveness. The less important must not interfere with the concentration of interest upon the most important, which in most pictures is the face. We also have mentioned that if any be unduly prominent they should be subordinated, their attractiveness lessened, either by lighting (if discovered in season), in development, or by the knife afterward. It is here that the ambitious student, in his attempt to improve a faulty piece, by partial or total elimination, should be on his guard. He must see to it that the work be not overdone, and that by toning down, because too bright or objectionable, it is not made too dark.

Pictures in Low Tones.

In making pictures in low tone, great care is necessary that the tone be rich and full, in default of which only muddy, black, and heavy prints will be the result. Accented lights will help to overcome these muddy tones, if used with care, so that texture and tonality are preserved.

Bear in mind that even the shadows, to say nothing of other dark parts of a low-tone picture, produce muddy effects unless gradation is present, excepting in a few of the very deepest shadows. This was the trouble with our earlier efforts in low-tone work, and still continues in the majority of the black backgrounds, in pictures made to-day, constituting a mass of gloom—unfeeling, unintelligent, and overpowering in effect. Put some life into the background, if only by flowing the back of the negative with ground-glass substitute and, with a tuft of cotton and yellow ochre, very slightly working-in larger or smaller masses so that, even while still dark, they will lessen the gloom by a semblance at least of gradation.

Rich Low-Tone Pictures.

A rich effect in low tone work is obtained by avoiding monotony. This is to be guarded against in work photographed in any key. This is accomplished by seeing to it that some parts of the ground or figure are more highly lighted than others. To avoid "spottiness" these higher lights should be massed, not of necessity over large areas, but enough to balance the picture without attracting too much attention. A little goes a long way. Richness is increased by a repetition of this scheme in some other part of the picture. It makes the whole piece a little more lively, aiding contrast, while enriching the shadows in which, as above said, some gradation is necessary to prevent muddiness.

The character of these masses, if obtained with the lighting, is largely governed by their own shape or form, which in itself adds interest. If obtained by working on the negative, then do not overlook the importance of making these worked-in masses of lighter key, interesting in their shape, in some such way as to suggest a form that is not symmetrical, for symmetry is decidedly objectionable in art. Also have the character of the masses, if more than one be employed, dissimilar.

Pictures in a Light Key.

Avoid a continual and unceasing gradation in "light" (and shade) tone, throughout the whole picture, when in a high key, for in this case, as with low tones, the results will be tame and monotonous.

In these "keyed-up" pictures have the light and shade a little more marked and snappy, at the same time being careful that it is not out of harmony in tonality. This art principle serves well as a brake to check a too liberal application of this suggestion. As in the case with low-tone work, it also produces variety and creates interest. Locate these enlivening tones of light and dark in various parts of the picture to produce richness.

The writer saw a reproduction of a very delicate painting in

decidedly high key, a group of fair children against a light background. The spots of dark were introduced at different parts of the picture by two dark-haired children, and a fairly strong shadow at another place. Result was beautiful. These dark masses were responsible for the success of the picture; on covering them the piece was insipid. When, however, a mass of dark cannot well be inserted in pictures of lighter key, it is sometimes advisable to introduce gradation to prevent flatness.

In pictures in the lighter keys the range of light values very often does not give a contrast of more than 15 to 35 per cent. out of a possible 100. The result, therefore, is more liable to be flat than when the range of contrast is greater, although not heavy, dark, and forbidding, as in pictures of the opposite key. For this reason it seems that a continual gradation throughout all parts of these pictures with little contrast should be striven against.

Breadth, in connection with tonality, the elimination of non-essentials, etc., is always desirable. Directions in arrangement and lighting (the beauty of simplicity), added to the elimination of unnecessary detail, flat shadows, and broad effects of light and shade, will do much toward making a success out of what otherwise would be a flat failure. This, in photographic art, appears to be the highest attainment in the production of high-keyed pictures.

The reader should not think that because I have advocated striving to produce the luminosity of colour values, and gradation of tone values, that I have here contradicted myself in advocating a practical disregard of some of these principles in pictures of the lighter key with slight contrasts. Even if my recommendation be accepted, it does not follow that values of all kinds are to be disregarded. On the contrary, some cases may call for even a greater amount of care that these principles be not disregarded.

Art does not require that every principle known to it should be employed to its extreme extent in all instances. It is all a matter of choosing the "handling" or treatment best suited for certain effects, and the producer of pictures by the lens should be able and resourceful in quickly determining how best to handle these various conditions as they arise.

Rules there are none in art, in the strict sense of the word. Certain rules have been proved to be good under certain conditions; yet even these have been broken and masterpieces have resulted from their breaking. Discrimination and judgment are left for the artist to employ. The study of correct "handling" is what he requires. He sometimes succeeds under certain conditions by violating principles which under other conditions it would be imperatively necessary for him to follow.

PROFESSIONAL.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, April 28 to May 3:—

PRINTING.—No. 10,946. Photographic printing apparatus. C. Haig.
MOUNTS.—No. 10,574. Meant for passe-partout framing of pictures and photographs. I. Joseph.

COLOUR PHOTOGRAPHY.—No. 10,831. Plates for making photographs in colours. E. H. Tarlton.

AERIAL PHOTOGRAPHY.—No. 10,956. Apparatus for maintaining a camera vertical in aircraft, and apparatus for registering angle at which a photograph is taken. A. Fawcett.

CINEMATOGRAPHY.—No. 10,729. Cinematograph apparatus. C. Bancarel.

CINEMATOGRAPHY.—No. 11,110. Cinematograph shutters. J. Crooks.

COMPLETE SPECIFICATIONS ACCEPTED,

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

ROLL-FILM CAMERAS.—No. 124,545 (June 13, 1918). The invention relates to roll-film cameras, and has for its object to provide improved means for operating the pins which hold the film-carrying

rollers in position in the camera, the means being capable of instant operation to bring the pins into their service and out-of-service positions.

The invention comprises the arrangement of the reel pins carried by the camera, so that they are adapted to be pressed into their operative positions (in which they enter the holes provided in the film-roller ends) against the action of a spring or springs and to be retained in such positions by catch pieces or their equivalents, with means for releasing the catch pieces, so that the reel pins are withdrawn by their springs clear of the film rollers.

As shown in the drawings, there are provided two movable reel

Fig. 1.

Fig. 2.

pins *a* for each film roller *b*, each reel pin *a* being normally held by a spring *c* acting on the cross pin *d* in its out-of-service position clear of the holes in the film roller *b*, so that the latter can be withdrawn from position and a new one inserted. The reel pins are moved into their service position by the application of pressure to their outer ends and are retained in such position by catch pieces *e*, each having a bevelled or inclined portion *f* upon which bears the pin *g* in each reel pin *a* when the latter is pressed inwards, so that the catch piece is forced outwards until the pin *g* passes beneath the catch piece, when the latter springs back into position over the pin *g* under the influence of the spring *h*. In fig. 2 the pin *g* is shown held beneath the catch *e*, and in fig. 3 it is shown clear of the catch. In the latter figure, the reel pin mechanism for the left hand end of the film roller is omitted, as it is a duplicate of that at the other end. The two catch pieces

Fig. 3.

may be operated simultaneously by movement of the inter-connecting spindle *i* having cranked ends *j* which engage the catches. The pressure of the finger on the tongue *k* on the spindle *i* turns the catches until they release the pins *g*, which then allow the reel pins to move outwards.

The improved arrangement may be applied to the reel pin which acts as the film winder, such pin and the corresponding one at the other end of the film reel being adapted, if desired,

for simultaneous release in the manner before described. Or the reel pin to which the film winder is attached may be an ordinary pin held in engagement with the film winding on roller by spring pressure, and the pin for the other end of the roller may be arranged in accordance with my invention, the catch being released by the pressure of the finger thereon. Samuel Poole Twemlow, Springfield, Sandbach, Cheshire.

FOLDING CAMERAS.—No. 124,636 (May 30, 1918). The invention is for improvements in or relating to cameras, and is particularly suitable for application to pocket cameras, though it is not restricted to these. According to the invention, the camera, having a base which folds up over the front, is characterised by the sliding front having a tail-board hinged to it, so arranged that when the front is pushed forward the tail-board engages the guide in the base, but when it is pushed back the tail-board extends out behind the body of the camera, and can be folded up against the back of the same.

Preferably the guides on the base are continued on the bottom of the main frame, to which the base is hinged, and the tail-board engages this portion of the guides as well as that on the base, and thus constitutes a strut between the base and the main frame, whereby the base is held rigidly in the extended position when the front of the camera is advanced.

The camera body comprises the usual rectangular frame A, having guides A' at the back to receive a dark slide B, and a baseboard C, which is folded over the front of the frame when the sliding front is being pushed in and the bellows collapsed. The baseboard C is hinged to the bottom member of the frame

A in the usual manner, and has guides C' on its upper face, in which slide the ends of the base D' of the sliding front. Other similar guides are provided on the bottom member of the frame A in alignment with the guides C'. The guided portions of the base of the front are longer than usual as compared with the thickness of the camera when closed, owing to the guided portions extending beyond the frame when the camera is closed. Hinged at E' to the back of the front is a relatively long tail-board E, which is also shaped to engage and slide in the guides C' on the base C. This tail-board E is of the same length as the camera back, and folds up behind the dark slide or the means for carrying the same at the back.

In operation, the baseboard C is first swung down as usual, and may be checked by any convenient butting means or by the usual folding strut F. The tail-board E is then folded down and pushed towards the baseboard, which automatically advances the front of the camera and extends the bellows, and the continued forward movement causes the tail-board to enter the guides in the body of the camera, and then also the guides C' on the baseboard C. The tail-board E thus bridges the hinge connecting the baseboard C to the body A of the camera, and provides a rigid connection between these two parts, so that the side strut or other means for limiting the downward movement of the base can be dispensed with if desired, though it is convenient to have something to arrest the downward movement of the baseboard whilst bringing the tail-board into position.

A spring detent G, mounted on the baseboard C, is provided to arrest the forward movement of the front at the position for normal focussing. In this position the detent G takes into a notch cut in the side of the tail-board E.

To prevent the tail-board E from falling below the horizontal position when it is folded down it is provided with a catch H, having fingers H', which project forward when the tail-board is in the horizontal position, and extend through and abut against upturned lugs D', carried by the base of the camera front to which the baseboard is hinged. The camera made as described may be of metal, and of such size as to go into the pocket, or it may be larger, and made of other substances according to requirements. Newton and Wright, Limited, 72, Wigmore Street, London, W.1; and Thomas Litchfield, 43, Lambton Road, Hornsey Rise, London, N.19.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

TUESDAY, MAY 20.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, May 13, Mr. W. B. Ferguson, K.C., in the chair.

Mr. W. C. Mann, chemist to Messrs. Thos. Ilfingworth and Co., read a paper on "Development Papers and Desensitisers"—that is to say, on the maker's problem of avoiding the effects arising from particles in the base paper having a desensitising action on the emulsion, and thus causing white spots in prints. He dealt very candidly with the difficulties which makers of development papers had had to encounter owing to the disturbance in the supply of raw paper-base. While particles of almost any heavy metal exerted a desensitising action on the emulsion, the most commonly occurring metals were iron and copper, the latter of much rarer occurrence than the former. Iron, however, according to the measurements of Mess and Sheppard, was twenty times as active as copper.

Tests for iron particles were made with either ferrocyanide or ferricyanide, that with a mixture of ferricyanide and nitric acid being most usually employed. A very delicate test consisted in the application to the raw base paper of an acid developer, such as formerly used for P.O.P., with addition of a little silver nitrate.

Emulsions, he continued, varied greatly in their susceptibility to desensitization by metallic particles, and the thickness and suitability of the baryta coating in the paper base were further factors. It was, however, possible to employ anti-desensitisers. Substances acting in this way were mummite and quinine. A considerable quantity of such anti-desensitiser required to be used in order to overcome the action of a possible maximum of desensitiser in every small area of the paper base; but by suitable choice of emulsion, baryta coat, and anti-desensitiser he had been able to produce quite faultless development paper with raw base which otherwise would have been completely unusable. He exhibited test pieces showing the complete freedom from white spots of developed prints on paper which yielded a large crop of iron spots under the ferricyanide test.

A short discussion followed, in which Mr. F. F. Renwick, Dr. R. E. Slade and the chairman took part.

On the proposition of the chairman, a hearty vote of thanks was accorded to the lecturer for his paper.

CROYDON CAMERA CLUB.

Attracted by an advertisement announcing that a society had been formed "for the scientific investigation of those results going by the name of 'psychic' or 'spirit photographs,'" the hon. sec. of the club, Mr. Sellors, immediately shadowed the hon. sec., Mr. F. Barlow, of the Psychic Society, who, not without difficulty, kindly arranged for last week's fixture.

To a crowded house Mr. James Wates, Ph.D., F.A.S., gave a

lecture on "Psychic Photography," illustrated by a large number of slides.

Now, a good deal might be said on a very interesting lecture, but a whisper from Wellington Street puts any account out of court, or into the editorial waste-paper basket, which amounts to the same thing. The decision appears to be wise, for a nodding acquaintance with psychics or spiritualism extending over a long period, indicates that any discussion on the subject is usually utterly fatuous, and contentious matter would be bound to be introduced into any report of the proceedings (very much so).

In further justification, let some points of view now held, seventy years after the birth of spiritualism as known to-day, be impartially enumerated. The sound, commonsense individual without examination dismisses the whole thing in light and airy fashion—"bally rot." Others brought into contact with it find this attitude impossible, and admit some phenomena, which they consider proved, as inexplicable, but deny any justification for the claim to the supernatural. In addition, many regard much which has been associated with, or appropriated by spiritualists, as tending to establish a morbid, but little understood, condition of the mind, and strongly advise avoidance of the subject by all. They further point out that practically nothing is known regarding the mind, and what is inexplicable to-day may be better understood to-morrow.

Ranged on the other side is a fairly large number who sincerely believe the various manifestations are of spiritual origin, and have adopted spiritualism as a quasi-religion, rejoicing in being able to penetrate beyond the veil, and perhaps communicate with loved and lost ones, the great human desire of all times. Counterblasts proceed from not a few of the orthodox, who allege that communication is established only with evil elements masquerading as benign, and they draw an obvious moral. Others, adopting a more neutral attitude, saying neither yea nor nay, affirm that not one jot of knowledge concerning the conditions existing beyond this life has ever been revealed, and sadly point out, assuming spiritualism to be true, then good-bye to the idea that the hereafter is on a higher plane than the present. Altogether quite a nice collection of assorted opinions and beliefs, which might still further be extended.

It may be permitted to add that a discussion followed the lecture, which was accorded a most hearty vote of thanks. Visitors from all parts were present, and appeared to be keenly interested. During the evening the secretary announced that the price of spirits had been advanced by one penny.

CATALOGUES AND TRADE NOTICES.

MESSRS. F. BRODRICK, LTD., 50, High Street, Charing Cross Road, London, W.C.2, send us their catalogue of their own special manufactures for professional photographers, among which is the drying machine which we recently noticed, developing and fixing tanks, enlarging easels and printing appliances, as well as the various patterns of the very well designed display tables and stands.

KODAK PRICE LISTS.—Messrs. Kodak, Ltd., Kingsway, London, W.C.2, have just issued two small price lists, suitable for distribution by dealers. One is of Kodak and Brownie cameras and accessories; the other of Premo, Graflex and Cirkut cameras. Dealers who may chance not to have seen these lists will do well to apply for them to the Kodak Company as a means of furthering sales during the present season.

Commercial & Legal Intelligence.

EASTMAN KODAK COMPANY.—In addition to the usual quarterly dividends of 1½ per cent. (being at the rate of 6 per cent. per annum) upon the outstanding preferred stock, and of 2½ per cent. (being at the rate of 10 per cent. per annum) upon the outstanding common stock, the directors of the Eastman Kodak Company have declared an extra dividend of 7½ per cent. upon the common stock—all payable on July 1—to stockholders of record on May 31.

IMPORTATION OF PICTURE POSTCARDS.—The importation of picture postcards, which has hitherto been dealt with by the Department of Import Restrictions, will henceforth be dealt with by the Department of the Controller of Paper (Board of Trade), 23, Buckingham Gate, S.W.1, to whom applications for licences should in future be sent.

News and Notes.

FIRE AT A STUDIO.—There was a serious outbreak of fire on the night of Saturday, May 10, at 11.39 p.m., at Bayley's Studios, Ltd., photographers, 16, Tottenham Court Road, W., as the result of a carelessly thrown down light. A back room on the second floor used as a workroom and the contents were damaged, whilst the rest of the floor of two rooms and the contents were damaged by heat and smoke.

MR. H. C. MESSER, of Castle Street, Salisbury, has supplied to the Mayor of that town enlarged photographs, which the latter is presenting as a record of two events connected with the war. One photograph represents the celebration of Empire Day, 1918, by a large body of British and Colonial troops in the Market Square, Salisbury. The other is a group of the local repatriated prisoners of war. The enlargements, which measure about 6 ft. by 3 ft., have been on exhibition at Mr. Messer's studios.

REVERSAL IN TANK DEVELOPMENT.

To the Editors.

Gentlemen,—We recently developed a batch of eighty dozen half-plates, all outdoor subjects. The plates all went through the same developer in our developing tanks, which are made to hold ten dozen plates. All the plates were developed satisfactorily except twenty-five plates. These came up positives instead of negatives, as the enclosed rough print will show. The plates appear to be slightly fogged, but on a suitable card would give good prints provided they had been negatives instead of positives. Is it possible to say how the plates came to be positives? In the case of a subsequent, also recent, lot of plates, some have turned positives instead of negatives. Out of a batch of eighty dozen half plates two dozen have come up positives and the rest are quite all right. They were all developed in exactly the same way, and, as far as we can see, there should be no reason why all the plates should not be all right. The most peculiar part about it is that one plate had been divided so that two exposures could be taken on the same plate. One half of this plate was a negative and the other part was a positive. Could this have happened in any way owing to the plate being fogged in the camera?—Yours faithfully,

W. BINNS.

Hollinroyd, Bispham, Blackpool.

[We shall be glad to hear if any user of tank development for large batches has had a similar experience. We can find no explanation of Mr. Binns's very remarkable result.—Eds. "B.J."]

REPRODUCTION FEES FOR PRESS PHOTOGRAPHERS

To the Editors.

Gentlemen,—It is certainly time that the present reproduction fee was increased.

London Press agencies are getting an increased fee, not per picture, but a bonus on the invoice.

If "Press Photographer" will join the Proprietors' Association of Press Photographic Agencies, 46, Fleet Street, E.C.4, he may also receive a bonus.—Yours truly,

"NEWSPAPER."

NEW SIZES OF SMALL CAMERAS AND PLATES.

To the Editors.

Gentlemen,—With reference to the announcement, "Quarter-plates to go," in your issue of 25th ult., I would like to add a few remarks to "Old Hand's" letter in your issue of 2nd inst. I am a colonial born of British parents, and am over here on military duty. I would like to point out that many of our men from overseas have purchased valuable cameras, amongst which are many fine quarter-

plate cameras. I myself purchased one valued at £25, also a quarter-plate enlarger valued at about £8. Now, Gentlemen, it is a fairly well-known fact by many tradespeople in this country who have had dealings with our soldiers that if the average colonial wants a thing he will have it, and no association is going to compel him to scrap his camera if he can get the plates and paper he requires.

If the British Photographic Manufacturers' Association will not supply him with the plates and papers, then don't blame the colonial if he secures his requirements from America or any other country. If such countries find the supplying of such articles will lead to trading in other photographic material there will be no difficulty in obtaining them. The Dominion to which I belong, and hope to return to, for years was flooded with German goods, and, unless Great Britain awakes to the fact, other countries will capture Germany's lost trade. Before it is too late, let the B.P.M.s' Association reconsider their decision to rule out the quarter-plate. Also it would be well for British manufacturers to have better control over the retail price of goods in the colonies. Why cannot the manufacturers have a stated retail price for material for sale in the colonies, making allowance for custom duties, cost of transit etc. It matters little to the average tradesman who sells the article whether it be of British or any other make, so long as he obtains his profit.

See to it, Mother Country, you supply your children in the colonies with the things they require, and at a fair and reasonable price; otherwise you will drive them to seek other trading fields. To lose the colonial trade may eventually lead to the loss of the colonies.—Yours faithfully,

"A DOMINIONITE."

To the Editors.

Gentlemen,—The attention of this Association has been drawn to the letters appearing in your issues of May 2 and 9 on the subject of the new standard plate sizes, and I have been requested by my council to draw your attention to the fact that your correspondents have evidently misunderstood the intentions of the Association in this matter.

First of all I would point out that there is no idea whatever of withdrawing from the market any of the old sizes of plates, such as the $\frac{1}{4}$ -plate size, which will all continue to be manufactured by the plate manufacturers so long as they are in demand, and that as far as the camera makers are concerned, it is not even their intention to discontinue the manufacture of their present model cameras in the old recognised sizes, such as $\frac{1}{4}$ -plate, but only when introducing new models to make them in the new four standard sizes in preference to any other sizes.

In fairness to the plate manufacturers I would further state that this is a question which has been raised entirely by the camera manufacturers, in order to reduce as far as possible the enormous variety of sizes in which cameras now have to be made, so that they may be produced on a quantity production basis of manufacture and thus be sold at the lowest possible prices consistent with the type of article. This standardisation of sizes, which it is intended as far as possible shall apply all over the world, is surely not only in the interests of the manufacturers themselves, but also in the interests of all camera users, as under present circumstances an Englishman travelling on the Continent or, say, in South America with a camera of English manufacture has the greatest possible difficulty in obtaining supplies of plates that will fit his camera, and the same thing applies to a foreigner, from any country where Continental size plates are in use, travelling in Great Britain or in any country where English sizes are the most popular.

Standardisation all over the world also carries the advantage to the manufacturer that instead of having to make two cameras of almost identical size (viz., the English and Continental corresponding sizes), he will only have to make one model which will be suitable for all foreign markets, and thus enable him to secure at least a fair share of the trade which before the war went largely to Germany.

It must also be borne in mind that the demand of recent years by photographers for cameras giving a picture of the oblong shape, which is certainly more pictorial than the old square-shaped $\frac{1}{4}$ -plate, has very greatly increased, and although this is not nearly such a serious matter as the other questions referred to above, it

surely is the correct thing for the English manufacturers to cater for what is in demand rather than to endeavour to keep to the old conservative attitude of the Englishman of never making a change if it were possible to avoid doing so.

If your correspondents will refer to the Association's letter which you published upon this subject, they will at once see that, although camera makers are requested to make all their new models in the four standard sizes it is proposed to adopt, in preference to the old sizes, yet there is no idea of creating such a situation as your correspondents seem to fear—viz., that the cameras they now possess may become obsolete and useless.—Yours faithfully,

ARTHUR C. BROOKES, Secretary.

British Photographic Manufacturers' Association.

May 14.

MONOMET-HYDROQUINONE DEVELOPER.

To the Editors.

Gentlemen,—Many formulae of the developer monomet-hydroquinone have been given in the "B.J.," but none have been given as to the time it takes to give a plate of the same density as when the same quantity of metol-hydroquinone was used.

Prior to the war I was fond of using the liford formula for metol-hydroquinone:—

Metol	30 grs.
Hydroquinone	45 grs.
Potassa metabisulphite	45 grs.
Water	10 ozs.
Sodium sulphite	1 oz.
Sodium carbonate	1 oz.
Water	10 ozs.

For use I took 1 oz. of each and added the same quantity of water. At the temperature of 80 deg. F. I noticed that it took 2½ minutes to develop a plate properly. Metol being dear, I reduced the quantity by one third and increased the hydroquinone similarly. I noticed that it took 3 minutes instead of 2½ to develop a plate up to the density I required, and, what was more, I found that the developer was particularly good for the Paget bromide paper.

Not being able to obtain metol a couple of years ago, I was offered "Monomet." I used the same formula, substituting it for metol, and developed for three minutes, but to my surprise I found that my negatives were very dense. I made some experiments by diluting the developer. I found that to obtain the same density as would be given by my old developer, I had to dilute with 2½ ozs. of water for every 1½ oz. of the Monomet-hydroquinone developer instead of 1½ oz. of water with the metol-hydroquinone. Thus it will be seen that the ratio of the strength of Monomet to metol is five to three.

My present formula is:—

A. Monomet	20 grs.
Hydroquinone	60 grs.
Potassa metabisulphite	80 grs.
Water	10 ozs.
B. Sodium sulphite	1 oz.
Sodium carbonate	1 oz.
Water	10 ozs.

The above can be made up into a single solution developer, it can be used as two solutions, and keeps well. I use 1½ oz. of A, ½ oz. of B, and add 2½ ozs. of water and a few drops of 10 per cent. solution potassa bromide, and develop for three minutes at 80 deg. F. For bromide paper, I prefer to dilute with an equal quantity of water, and develop for one minute.

Hoping that some of your readers may profit from the above.—I remain, yours faithfully,

TAN HOCK ANN.

Treasurer, Penang, Straits Settlements, April 2, 1919.

FORTHCOMING EXHIBITIONS.

April 17 to May 22.—Hammersmith Hampshire House Photographic Society Annual Exhibition. Two open classes. Joint secretaries, J. G. Abrahams, 41, Hamilton Terrace, London, N.W.8; A. H. Page, 12, Laine Grove, London, W.12.

September 13 to October 11.—London Salon of Photography. Entries close September 2. Hon. sec., 5a, Pall Mall East, London, 1

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

- L. T.—We take it that you did not supply any photographs at all, not that you supplied one that was unsatisfactory. In this case, there can be no doubt at all that the sitter can legally demand the money to be returned.
- G. B. B.—The London address of the Bausch and Lomb Optical Company is 37-38, Hatton Garden, London, E.C., but most probably they would not care to take on a little job of this kind, and you would want to go to an apparatus repairer such as Messrs. H. T. Ball and Co., 51, Berwick Street, Oxford Street, London, W.
- N. E.—We think it is pretty clear from what you say that by suing Mrs. L. in the county court you would get your charges, and she would have to pay costs. Obviously, by offering you a sum of money she has admitted the debt, and therefore it would not be necessary to establish the fact whether she had ordered the work or not; it would merely be necessary to establish what your charges were for the three prints, which, we take it, is what you want to do. No doubt if you have a solicitor's letter sent to Mrs. L., pointing out that she has no defence if it came into the county court, she will readily pay the amount and the solicitor's costs.
- B. E.—Motor vehicles photographed out of doors call for a quite different lens from one suitable for interiors and workshops. For the former you want as long a focal length as you can afford, in order to make a distant standpoint for the camera and so avoid exaggeration of the size of the bonnet in comparison with the size of the body. A 20-in. lens is none too long for a 12 x 10 plate for this purpose. No need to have an anastigmat, an $f/8$ R.R. is all you want. For interiors and workshops we advise an $f/6$ anastigmat of from 10 to 12-in. focal length if you are confined to one lens, but if you can run to two, you had better get a wide-angle for this size of plate of about 8- to 9-in. focus, and one of, say, 12 or 14-in. for general work, the latter might be an $f/6$ anastigmat, but an $f/8$ R.R. would be very nearly as good.
- O. N.—1. It is advisable to apply for one. The address for your district is Iddesleigh Mansions, London, S.W.1. 2. No, except on stationery and mounts. But you will require to register the business under the Business Names Act. The fee is five shillings. If you cannot obtain the necessary forms from your local post office, you can get them from the Registrar of Business Names, 39, Russell Square, London, W.C. 3. At least four 1,000 c.p. Six would be better. 4. In a curve between 7 and 8 ft. from floor extending from centre of front of background 8 ft. from it to 5 ft. from edge of background. We should advise a thin calico diffuser. 5. "The Studio and What to Do in It," by H. P. Robinson (Hiffe, 3s. 6d.). No book obtainable on posing. Our publishers supply a small manual on sketch portraiture, by J. S. Adamson, price 8d., post free.
- E. M.—The cause of the pinkish stains is probably insufficient citrate in the toner. Perhaps you have not the right quality of citrate. At any rate, it is evident that you want more of it.

Papers vary in this respect, and unfortunately one cannot compare those of the present time with pre-war qualities, on which the formula was based. We can give no explanation of the irregularities of toning, but think perhaps they are not thoroughly fixed (in two baths in succession), and washed for half an hour or so in five-minute changes. The Ferguson process is quite a reliable one. The only alternative for red tones is to sulphide tone in the usual way, and then to treat the prints in a gold-sulphocyanide toning bath, as used for P.O.P. Messrs. Wellington, who have advocated this method for a long time, give some instructions in their handbook.

- A. H.—2. If you are enlarging to large size, say 20 by 16 and over, and may be working from dense negatives, you had better have a small arc lamp, a very good model of which is supplied by the Westminster Engineering Company, Victoria Road, Willesden Junction, London, N.W., very widely used for enlarging, and as good as any you can have. 3. Impossible to say, as it depends solely on the scale on which you are enlarging. For a half-plate negative you would want a lens of about 9 in. focal length, and you can reckon the space required in front of the enlarger by roughly taking it that for every degree of linear enlargement you will want 9 inches. Thus, if you are enlarging four times, you will require three feet space in front of the enlarger. Really you require to allow also about another foot. 4. As good as anything is an R.R. lens of about 9 in. focus. 5. As regards the camera, if you are taking single portraits with plenty of space, a half-plate lens of about 9 in. focus will answer quite well for the small sizes, but if you are taking anything else in confined situations, you will want lenses of correspondingly wider angle—that is to say, a lens of which the focus should be a little longer than the long side of the plate. 6. It all depends on the space you have available. If ample space, you can; if the space is prescribed you will want different foci. See table in the "B.J. Almanac," which will tell you exactly what you can do. 7. Yes, certainly. For copies on to half-plates, 9 in. lens will do very well indeed, or any R.R. lens; for small plates, of focus about 1 in. or so longer than the long side of the plate. Extension of camera should be at least double the focal length of the lens, unless you want to make enlarged copies in the camera, in which case it must be a good deal more.

The British Journal of Photography.

Line Advertisements. Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.

(No reduction for a series.)

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.
Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.
Displayed Adv'ts should reach the Publishers on Monday morning.
The insertion of an Advertisement in any definite issue cannot be guaranteed.

SUMMARY.

In his article this week "Practicus" deals with mounts and mounting, discussing the artistic choice of mounting papers, as regards tone and colour, and the practical measures of trimming and mounting by both the dry and wet methods. (P. 278.)

The requirements needing to be fulfilled in photographs taken for the purposes of evidence in law courts are the subject of an article by a legal photographer which we quote from "Photo Era." (P. 276.)

M. Equer and Cousin, of the French Photographic Society, have made a series of measurements of the variation in speed of a focal-plane shutter over different parts of the plate. The variations disclosed are considerable. (P. 280.)

In a leading article we seek to set forth some of the causes created by the war period which may have their effect upon the photographic portrait business, and more particularly upon studio operators not in business for themselves. (P. 274.)

In the course of the concluding portion of his article on colour Mr. A. Vernon Goldbold has some practical hints to give. (P. 275.)

A table of the quantities of toning bath to be used for various numbers of different sized prints has been published by Messrs. Rajar, Limited. (P. 283.)

A Swiss correspondent sends us some notes on the opportunities for trade in British photographic materials in his country. (P. 283.)

Major Laws, of the Photographic Section, R.A.F., is to read a paper on aerial photography before the R.P.S. on June 5. (P. 286.)

We are glad to be able to say that steps have been taken to prohibit the importation of German cameras by officers in the Army of Occupation. (P. 274.)

The question of applying for a charter of incorporation was discussed at the last council meeting of the Professional Photographers' Association. (P. 284.)

Mr. George Hana, ex-President of the P.P.A., has had to undergo a serious operation, and is progressing well. (P. 286.)

According to an American journal, a photographic method of recording wireless messages has been successfully worked out by an American engineer. (P. 287.)

A correspondent of the "Pharmaceutical Journal" has recommended a solution of quinine in alcohol as a plate backing. (P. 286.)

The mineral naphtha used in denaturing spirit is no doubt a cause of scummy deposits on negatives additional to lime salts in the film as a result of washing in water containing them. (P. 273.)

EX CATHEDRA.

Colonial. On behalf of our publishers, we must ask intending advertisers in the forthcoming Colonial and Foreign Number of June 6 to note that the last day for the receipt of display advertisements, and for the alteration of copy in standing advertisements, is Thursday, next, May 29. The volume of advertising matter in this number is such that an earlier closing of its pages, so far as displayed advertisements are concerned, is imperative, and advertisers will very greatly facilitate the convenience of our publishers in getting out the issue if they will give their orders and supply copy at the earliest moment within the next few days. The dates for the receipt of small prepaid, undisplayed advertisements remain as usual, that is to say, they can be accepted up to noon on Wednesday, June 4, but here again, in view of the great bulk of the issue, it is even less possible than ordinarily to guarantee their appearance. It is advised that such small advertisements should reach our publishers not later than Monday or Tuesday, June 2 or 3.

* * *

Spirit Drying. The paper by M. L. P. Clerc, which appeared in the "British Journal" of last week, is a valuable contribution to the cause of one of the minor troubles in photographic processes. While M. Clerc's experiments make it abundantly clear that the presence of lime salts in the film of a negative or print, due to saturation by lime containing water, is the cause of white markings, it may nevertheless be thought that lime in the water is not the whole cause of the whitish deposit which is liable to occur in drying plates or prints with spirit. The mineral addition which is made in denaturing spirit is a cause of the milkiness which is produced when such spirit is diluted with water, and we think there is no reason to doubt that part of the whitish scum which is produced in drying negatives with methylated spirit arises from this cause. Probably it differs from the lime deposit in being largely superficial whilst the latter extends through the substance of the film. Gentle abrasion of the dried negative surface by preparations such as Baskett's reducer or Vanguard "Frictol" will easily remove such superficial deposit, though it will not touch any precipitated lime salts in the film itself. The behaviour of a negative under this treatment will, therefore, give some clue as to the cause of the deposit. Incidentally, M. Clerc's measurements of the number of prints which can be dried under various specified modes of treatment in a given quantity of spirit emphasise the very great economy resulting from draining water from the prints before immersion in the spirit, and of draining spirit from them after immersion. Blotting or squeezeing of the prints would show still better

results. The figures mark the considerable amount of liquid which is retained by a print but can be readily removed by simple mechanical means. It will be remembered that many years ago MM. Lumière showed the advantage of the same principle in washing prints.

* * *

Import Regulations.

A memorandum of the Board of Trade, issued on Wednesday in last week, contains a list of a considerable number of classes of goods, restrictions on the importation of which are to be removed. Among photographic requisites the order refers to the following:—Ferrotypes plates, camera shutters, positive papers, and cinematograph cameras. Presumably "ferrotypes plates" refers to the polished plates employed for squeezeing, although it may be interpreted as applying to the sensitive plates used in ferrotypes cameras, of which formerly there was importation on a considerable scale. The removal of restrictions on the importation of shutters will undoubtedly be welcomed by the camera-making trade, but it is doubtful if the same feeling will extend to the unrestricted introduction of positive papers by the makers thereof, whose costs at the present time are probably much in excess of those of American manufacturers. It is possible that the effect of the Order may be a fall in the prices of printing papers. Cameras fitted with lenses are to be imported under licence only exceptionally as and when required, but all other photographic apparatus, with the exception of that already mentioned, is to be admitted at the rate of one-third of the 1913 importations in proportionate quarterly amounts.

* * *

No Cameras from the Rhine.

We are glad to see in our contemporary the "Photographic Dealer" that steps have been taken to put a stop to the offering for sale in London of cameras bought from the German dealers by officers of the Army of Occupation. The question was raised in the House of Commons by Lieut.-Col. Moore-Brabazon, and though Mr. Churchill made a very unsatisfactory reply, it now appears that he took steps, on particulars given to him, to request the military authorities on the Rhine to put a stop to this trading with the enemy. Mr. Arthur Brookes at the Photographic Dealers' Association mentioned a case of an officer who had been prevented from bringing a camera purchased from the Germans back with him to England, so it seems that the traffic will cease or, at any rate, be reduced to quite negligible proportions. We are glad to hear from several dealers in second-hand apparatus that they will buy no more of these cameras, and we can assure them that we shall take every precaution to prevent their being offered for sale in our advertisement pages.

* * *

New Standard Small Sizes.

The letter from the British Photographic Manufacturers' Association, published in our last issue, effectively answers recent correspondents who professed to discover in the earlier announcement of the Association the desire to victimise plate users for the benefit of the makers. On the face of it, such an interpretation was absurd, for where a large number of cameras of a given size exists it is obviously to the plate-maker's interest to supply plates for them, and anybody who knows anything of the present position in the camera-making trade appreciates the fact that camera-makers have good reason not to concur in a policy which will render existing cameras obsolete. As we pointed out at the time, the change is plainly one which must take place gradually, and we now have it from the Association that the transition will be rendered still slower by the fact that camera-makers will continue to manufacture present models of apparatus in the old sizes,

and are asked to adopt the new only in the case of fresh patterns of camera. Anyone who read the original announcement carefully should have been under no misapprehension, but the Association's letter usefully emphasises some of the advantages which in time will result from its policy.

* * *

Focal-plane Shutters.

The paper by MM. Equer and Cousin, communicated to the French Photographic Society, which we print on another page, is an interesting contribution to the technics of the focal-plane shutter, although the measurements were made of a type of shutter quite unfamiliar to us in this country in which the slit forms part of a rigid plate instead of a flexible blind. The effect of mass in causing acceleration of the slit as it travels downwards from top to bottom of the plate is one which theoretically, of course, applies also to a flexible blind, although we should expect to find that its influence would be small in comparison with the fairly constant friction existing during the simultaneous coiling and coiling of the blind. It may be hoped that MM. Equer and Cousin will carry out their experiments on commercial patterns of focal-plane shutters of the roller-blind type.

THE TWO WAYS.

WE were reminded the other day of the directions in which the business of portrait photography has moved during the last few years by coming across a leading article*, which reviewed the situation and apparent tendencies at that time. Then, as now, portrait photography included within itself the so-called "high-class" and "cheap" businesses. But the latter particularly were of a somewhat different kind. The establishment producing portraits at exceedingly low prices was then only in its initial state of development, for the most part producing the small portraits sold as "sticky-backs"; and very largely an element in the business was its peripatetic character. It was assumed, and then no doubt quite rightly, that the local demand for portraits of this kind was soon satisfied, so that having exhausted the custom of one large town the people in the business would carry their not very elaborate equipment to another. At that time, too, we had another kind of cheap photographer, the amateur-professional, or "backyard" man, engaged during the week in his ordinary occupation and making a business in his leisure of such portraiture as was within his capacity, and for which he could find a market only on account of the small price he charged for it. Fortunately, the development of the legitimate cheap portrait business has gone a very long way towards extinguishing his kind. In this glance backward it is instructive to note that along with the increase in cheap photography there has been, as we ventured in the article to predict that there would be, at least a corresponding development in the high-class studio. The interval has witnessed the arrival of some men who have come to take a front-rank position as photographic portraitists, although they entered the business altogether without a preliminary training in the ordinary studio. Their work has achieved success entirely on its merits, and has not been without its effect upon those who previously sought to cater for the most cultivated class of customer.

So much for the immediate past. What of the future? Let us say at once that we do not take a pessimistic view of the prospects of the photographic portrait business even in the years of war-aftermath which are opening. Perhaps at no time during the last half century has it been

*"Under which King, Bezonian." "B. J.," Jan. 25, 1907, p. 59.

less easy to forecast the outlook for a business like photography under the exceptional conditions which have been created by nearly five years of war, and, still more, industrial dislocation. We are living in a time of flux where forces are in operation greater perhaps than any which have moved in England since the Civil War. Industrial magnates who expected to end their days plain commoners sit in the House of Lords! Mr. Smillie catechises ducal landowners; Royalty goes slumming, and Labour leaders are called in for conference on high matters of State. Nevertheless, amid the cross currents of such a moving time certain elements can be discovered which have a bearing upon the prosperity or otherwise of the photographic portrait business. One of these is the immense advertisement which photography, by its service to the Army, has received. The mere fact that photographs taken from the air are the means of saving thousands of lives gives an added status to a photograph as such. We may not be able to analyse the mental process, but we can recognise the conclusion. Then photography has been enlisted to show the public at home what war is like. The many war exhibitions of photographs in London and throughout the country have rather overshadowed, in this field, the arts of the painter and draughtsman, from whose work in the past the public has formed its impressions of warfare. Then it has to be remembered that the putting of millions of men into uniform and sending them overseas has provided among the masses of the public the frequent occasion to visit the photographer's; the same thing applies to the multitudes of W.A.A.C.S., W.R.E.N.S., and W.R.A.F.S. recruited during the latter phase of the war. The stimulus thus applied to the wish to have a photograph taken has been a far greater factor in bringing photography and the people *en masse* together than even the scheme of "Snapshots from Home," which worked in a different sphere. Concurrently, too, with these influences is the greater distribution of money among labour. The thirty millions which the miners have added to their wages will be spent on photographs among other things. A greater expenditure on articles which hitherto have been regarded as more or less luxuries is to be looked for among the working classes.

Thus, while we are very far from thinking that there is to be a lesser demand for portraits of the highest artistic excellence such as are represented by the work of our leading men, we think we foresee a greater and greater patronage of the studios catering for popular tastes at a popular price. It is in reference to this tendency in photographic portraiture that the photographer, be he proprietor or operator, whose work falls into the

category of "good average middle-class" needs to revise his ideas. He may, and in our experience very often does, despise the cheap work. We think he fails to recognise that the cheap work is constantly improving in quality, that at the present time a fair proportion of it is very good, and is cheap for the reason that its production is organised upon business lines to which many a photographer of the passing generation is a stranger. It is not easy to specify with anything like exactness the personal and technical qualifications which make the average portrait photographer. Largely he is born of an interest in the technical processes, negative-making, printing, and the like, has some aspirations after art though little appreciation of its essentials, and next to no training in it. Add to these a business instinct, which varies greatly among individuals but in many cases is not highly developed, and you have perhaps a rough picture of the general type of photographer—one who loves his occupation for its own sake and is averse from having it divided off into watertight compartments like a well-organised factory. Nevertheless, to a very large measure we stand, so we think, at the present day at the parting of the ways, in one direction along a path which is highly individualistic and offers success only to the man of genuine artistic capacity; in the other, along well-planned commercial lines designed for the cheap and efficient production of portraits the quality of which will improve as time goes on and will become such, even if it is not so now, as will satisfy a large proportion of the customers to be found in the middle classes. A consideration of these present-day tendencies is perhaps more important to the photographer seeking employment as a studio operator than to men in business for themselves in towns of small or moderate size, where their customers are those of the more or less well-to-do middle-class. The employee, and at the present time many are would-be employees, needs to consider that the field for him in the future may lie in the cheap portrait studio; the smaller proprietor is fortunately in the position that he does not rely solely upon portraiture for his takings, but obtains a substantial proportion of his income from work done away from the studio, and often including much of what is generally called "commercial photography." We venture to suggest that it is to his interest to cultivate this branch of work by all the means which are available to him. As we have often said during the past three or four years, we think there is great scope still for photography in this field, and that altogether the prospect for photography in these changing times is not one to discourage any of those connected with it so long as the possible and probable outcome of the forces at work is recognised.

FOURTEEN POINTS ON COLOUR.

(Continued from page 262.)

PERFECTLY transparent colours are too powerful, sometimes look quite sickly, especially if yellow; therefore always use a little body colour in your backgrounds to give atmosphere to keep them from coming forward, as it is unlawful to suffocate people. The most suitable colours are the neutral tints like gray, brown, delicate pink, olive, russet or citrine. These also go well with any mass of black. For vignettted backgrounds:—

Blue gray shaded with brown.

Green shaded with burnt sienna.

Neutral tint shaded with yellow or green.

Olive green shaded with brown.

9. Flesh is best represented by simple tints nicely gradated and not broken up. A patchy juxtaposition of primary

colours is all very well for small miniatures, but is not suitable for colouring a photograph of medium size. If the colour of the face is too brilliant it will lack refinement, and if beauty is lacking a nice quality of colour will give it charm. When Reynolds, speaking of colour, told his students to think of a peach, he meant the direct condition of flesh was peach-bloom, surroundings cruder, and lips as compared with dry-bricks to look like fruit; therefore he very pithily described what he aimed at himself. Do not be afraid to colour the ears with a little red to keep them back and force the nose forward; don't get them purple, as this will give them a frozen appearance. The eyes and mouth have the most colour, then the cheeks; keep the colour clean, avoid hot foxy colour, leather colour and fever colour. Don't forget a soldier looks ridiculous with a

lady's complexion. Course brushwork on the face always makes the flesh look like a sheet of crumpled notepaper. Use a white enamel or china palette, so that the transparent and semi-transparent tints can be better seen.

10. Now to a question of a little reform as a means of bringing about better results and a better reputation for coloured photographs. One of Whistler's propositions was that a work of art should be "finished" from the beginning. This is well understood by operators as regards B. and W., but colour is always an afterthought, an afterwish by the patron, whereas good work can only be done by making it a forethought. It is suggested for studios to announce special sittings for colour arrangements—no extra expense, merely the use of a panchromatic plate, some forethought and advice. Costly curtains and screens such as Royal Academy artists favour are not advocated. Procedure after this style: A lady takes advantage of the studio's announcement for a colour sitting, and is dressed in blue; a background is let down, preferably of a panelled room; she is posed removing a plate of oranges from a table. That picture would lend itself to colour.

The present method is something like this: A lady in furs wishes for a standing position, and is taken against a landscape that happens to be down. The picture is passable in B. and W., the lady likes the expression, an enlargement is ordered to be coloured. The result unfortunate, because the colour emphasises the landscape.

A lady is taken in evening dress against a strong cloudy background. It looks very well in B. and W.—an order is given for one coloured. The colour of the clouds translated by the artist as a storm makes the lady look foolish.

Much can be done by painting in and painting out, but if a coloured photograph is to show a nice clean, even finish and surface and general craftsmanship it must be finished from the beginning. Ladies love a change of dress, whether it really suits them or not. It may happen a woman of forty, with a sallow complexion, in a blue blouse, has a sitting, afterwards asking for a coloured enlargement. She gives the colours; her friends know that particular blouse is blue, and blue it's made. The result is cruel, because the blue intensifies her yellow face. If forethought was colour and the artist is consulted he will probably discover by conversation that the lady had at home a more suitable dress of yellow-brown and a string of yellow beads—an easier picture to colour with satisfaction all round. The same consideration should be for children; and how pleased parents are if the child makes a picture, more so if colour can be effectively applied.

11. Until the great need for the standardisation of the terms describing the quality of colours is filled, and an accurate system of colour notation is invented the artist must see the sitter. Where this is brought about a great difference will be seen in

the truth of colour recorded; and if an artist is not on the premises the occasional artist should be in attendance by appointment. It used to be quite an event in olden times to have one's portrait recorded in colour, and why not to-day?

A special fee will have to be charged to meet the time taken up, but the result will be worth it. The plain man in the street can see the difference between Bond Street work and the product of the "Whitechapel gentleman" when the two are together, although he does not know why.

12. If Whistler had run a studio he would have announced:

Maker of Portraits.

Projected Pictures.

Symphonies in Silver-grey and Black.

Harmonies in Golden Brown.

Colour Arrangements by Appointment.

Silhouettes in Nocturne Tints.

And would have displayed his "projects" after the manner of high-class studios of to-day, displaying just one or two coloured specimens as something choice, which is far more effective than the shops that crowd coloured enlargements into their windows like the unloading sale of a picture factory.

13. Tinting vignettes in various colours in the same way as cream toning is done by the hypo-bath is suggested. Whistler selected coloured papers for his pastels, not to avoid "fatiguing the paper," as he put it, but that a fine effect could be got by easy means. For instance, a few touches of scarlet on blue-green paper is a most striking harmony. Suppose the aim is to make an enlargement from a vignetted head and shoulders of Marshal Foch as an attraction for the window. The artist proceeds to make the print himself, to save time afterwards, as few printers can make a soft vignette. Then by means of the hypo-bath he tints the paper or takes the print out of the bath and sponges it over with a dye of soft blue-grey, then leaves it to be washed and mounted in the usual way. The face is coloured by the oil, wax or pastel method; the gold braid and Army ribbons touched in. It will be seen by getting rid of the surrounding whiteness which is so common, and adding a tint the touches of colour tell like jewels, and have quite a different appearance to the usual dust cloud raised by the airbrush. A girl in a green dress would have a green-grey ground tint similarly with other subjects.

14. Colour will be wanted to liven the display and to give variety if the suggestion of local exhibitions for professionals is carried out—what Whistler would call "an heroic kick" to improve business, a stimulant to good work, a counter-attack to the canvassing tout. With a couple of borrowed war photographs in colour to help the attraction the public would remember for a long while where to go for good work. Photographers would meet as in the market-place, and other benefits would accrue.

A. VERNON GODBOLD.

PHOTOGRAPHS AS EVIDENCE.

[The use of photographs in legal actions, not simply for the purpose of illustrating and facilitating the evidence of witnesses, but in providing evidence of a different kind, is viewed with more favour in American Courts than in those of this country in which the judicial mind, so we think, is less open to the acceptance of fresh practice. Therefore, in reprinting the following very practical notes on legal photography from our Boston contemporary, the "Photo Era," we should make it clear that we do so, not with the idea of suggesting a remunerative branch of business to photographers, but by way of adding, on however small a scale, to the weight of testimony in favour of the qualification of the photograph to have its place in providing evidence, which may often be more reliable than that of the human witness.—Eds. "B.J."]

THE value of photographs as a means to bring the scenes, surroundings, and conditions that existed at the time of a crime to the direct attention of a jury seems to have been overlooked in many cases by the lawyer and the photographer. I believe that this is due to two reasons: first, the lack—on the lawyer's part—of knowledge of the value of photographs as

evidence; and, second, to the lawyer's inability to obtain the services of a photographer who really understands how to photograph so that his prints may be admitted as evidence. I have made a careful study of this branch of photographic work for ten years, and I will endeavour to explain some of the details of the requirements to make a photograph of legal

value in a case. I have had my photographs introduced as evidence in many kinds of cases covering accident, damage, attempt to defraud, larceny, and murder. I will give a few cases to show how very helpful and important photographs proved to be in establishing certain legal points.

There are some things with regard to the camera which will be understood by the photographer, but not by the lawyer. For this reason, I have made it a practice to have a "get-together" meeting, with the photographer and the lawyer as the interested co-workers. At such a meeting both can come to an understanding as to what is necessary to make a photograph of value, and what questions can be used to ensure the photographs being admitted to the court-proceedings; or, in some cases, what questions can be used in the cross-examination to cause the "other side's" photographs to be disqualified.

There are, I find, eleven important points to remember with regard to using the camera which, in my opinion, are absolutely necessary. Although these are by no means all that are necessary to bear in mind, they will cover automatically all other questions that may be brought up in the Court. By following closely the points that I will try to give, the photographer may be very sure—in fact positively certain—that nothing can or will be brought out in the cross-examination which will cause the Court to rule against his photographs.

Nothing of Importance can be Changed in the Scene.

That is, the negatives should be made as soon as possible, so that everything at the scene of the crime may remain exactly as it was at the time. If, however, considerable time must—for some reason—elapse before the negatives can be made, the photographer must be able to swear that nothing which has any bearing on the case has been changed. This is the reason that I have made a practice to keep a camera with plates and accessories that I may need—including flash-pan and powder, fifty-foot tape and compass—all packed in carrying-cases, ready for immediate use, either day or night.

Angle of View as that of the Eye.

It is very important that the lens should include about the same angle as the eye, for either an increased or decreased angle will tend to change the relation of objects shown in the picture. Now the average angle of the human eye is thirty-five degrees, so that for a 7 x 5 plate one will need a lens of 11 ins. focal length—this will give thirty-five to thirty-six degrees; on a 8½ x 6½ plate a 13 in. lens will give one thirty-five to thirty-six degrees, and on a 10 x 8 plate a 16 in. lens will give thirty-five to thirty-six degrees. Here, let me say that I have found the 10 x 8 print, linen-mounted, to be the best for all-round Court work, as it is large enough to bring out fine detail clearly, and is not too large to be handled easily.

Camera must be Level.

It is absolutely necessary that the camera be level, as a slight tilt will give vertical lines as not vertical and in some cases will cause one's photographs to be of no value whatever. Consequently, I say "use a level." I have in mind a case which was an excellent example to prove my point that I shall mention later.

Camera Back Vertical.

Every photographer is familiar with the leaning-effect that is produced by pointing the camera either up or down; and he knows that this same effect can be produced by too free a use of the swing-back; so that to show a view or an object as it really is one must have the plate exactly vertical. Then if, for example, a chimney is leaning slightly, it will appear and should be shown as leaning in the photograph.

Camera about on the Level of Your Eye.

In nearly all things that we see a change of effect can be noticed if one raises or lowers the viewpoint; and, in some

cases it is very important to be able to swear that the photograph is what a person would see at a certain place. For this reason it is important to have the lens of the camera on a level with one's eye when the exposure is made to give the true perspective.

Time at which the Picture was Made.

The exact hour and minute when an exposure was made is not absolutely necessary, as I have found that to say that a negative was made between the time of 1 and 1.15 p.m. is definite enough. In most cases as small an allowance as possible should be made to cover slight variations of time in watches or clocks.

Colour-Sensitive Plate Necessary.

It is well understood that the plate commonly called an "ordinary" one, sees only the blacks and whites in a subject at their true value, and it registers all other colours in tones that are, many times, exactly opposite to that which they should be. For example, red is shown as nearly black, and blue is white. This fact will give an entirely different idea of a scene than the one wanted; but this difficulty can be overcome by the use of panchromatic or orthochromatic plates and ray-filters. The use of these plates is familiar to most photographers, but for the benefit of those who have not used them detailed information regarding them may be obtained from the plate-manufacturers.

Making and Finishing Done by One Person.

This is important in that it saves calling more than one person as witness to the photographs at time of trial.

Exact Location of Camera.

In locating the camera definitely as to where it stood at the time of making the exposure, be sure to make all measurements from fixed objects and also to note carefully the direction in which the camera was facing. For example, a good description of location would read something like this: "Camera stood 6 ft. west of the west edge of the concrete-walk on the west side of Main Street and 52ft. 7 ins. south of the south edge of the concrete-walk on the south side of State Street. Camera was pointed a little east of north-east, facing across the intersection of State and Main Streets in the town of — County of — and State of —. In all of my measurements I am allowing a possible error of 1 or 2 ins." This is clear, and I think that from this description of location a stranger could locate exactly where the camera stood.

No Retouching on Negative or Prints.

It is easily understood why no retouching can be done, as the prints must be true photographic reproductions of what they are intended to show.

The prints must be sworn to in the witness-box by the photographer who made them. In some cases his disposition can be used, although it is much better to have him there in person.

Photographs can be used in nearly all cases that come up for trial, viz.: accident, damage, attempt to defraud, larceny, and murder. For example—a case of accident. At about ten o'clock p.m., on a road from a famous "wet" town, a motor-cyclist collided with an automobile; result, the driver of motor-cycle was killed. The automobile driver called me out at once; and before anything was moved we made flashlights to prove that the automobile was on the right-hand side of the road—where it belonged—therefore the motor-cyclist must have been on the left side to run directly into the front of the automobile. At the trial further evidence brought out the fact that the motor-cyclist was partly intoxicated; and, with his photographs to back up his statements, the automobile driver freed himself of a large damage claim.

Damage suits are common, and usually well adapted to the

court use of photographs. I had prints in a case where payment was withheld for a silo, the claim being that the silo was crooked, cracked, and a source of danger to an adjoining barn. Prints from negatives made with the lens facing directly north, west, south, and east, with camera level and swing-back straight, showed that the silo was straight but the barn crooked! A telephoto-lens proved that cracks near the top of the silo did no particular harm, and these facts brought in a judgment of the full amount due to the contractor, with no deduction for any damages.

Insurance companies in particular are subject to attempts to defraud by arson. I had a case where a house insured to the limit burned under very suspicious circumstances. I made photographs that showed four distinct fires with no connection between them. Old, broken furniture was placed in the house—the good furniture was in a shed at the rear; and in one room I photographed two glass gallon jugs with a few ounces of kerosene in each. These prints were so convincing to the jury that the person who had the fire is now serving time at the State penitentiary.

I had an interesting case of larceny where two windows of a house were broken in an attempt to release the window catches. A man was arrested as he was leaving the house, after the people had heard the windows broken, but had seen no one near them. The windows were broken by the use of a brick, and photographs showed brickdust and particles around the break in the glass—they also showed the dust particles around one of the suspect's pockets. The man is now doing time for attempted burglary.

Murder cases offer unlimited opportunities for the use of

photographs, as in these cases all points relative to the case are sifted to the finest possible degree, and the photographer has a good chance to show what he can do. I had a case where, at a farmhouse near a town, a young man was shot and killed, and an accident claimed. The interested persons asserted that the young man drove up in a machine with several others and stopped to talk with his friends at the farm—they were all Italians. While his friends talked he got out of the machine and went into the house. As he was coming back from the house one of the men who stood beside the machine fired a revolver which he was holding behind him and accidentally shot and killed the young man who was coming from the house. Their main witness claimed to be standing at the corner of the house where he saw it all happen. A photograph from the place where he claimed to be standing proved that he could see *nothing* on account of a row of lilac bushes between him and the road! A photograph from across a small field supported one of the claims of a witness for the State that he was not too far away to see—as he asserted that he did—that it was not an accidental shooting. The person who did the shooting is now doing time for manslaughter.

I could give case after case where photographs have showed themselves to be of practical value to prove claims and to bring actual scenes to the jury. In all cases photographs are worth many times their cost. Photographs as evidence are worthy of careful study on the part of the lawyer and the photographer. By careful study and consideration each can add to his reputation as an expert in his chosen line; and in addition each can add a few dollars to his bank account.

LA VERNE T. RYDER.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).

The Postcard Studio (March 14).
The Printing-Room (March 21).
About the Reception Room (March 28).
Home Portraiture (April 4).
Portable Studios (April 11).
Copying (April 18).
Handling the Studio Camera (April 25).
More About Lenses (May 2).
Enlargements (May 9).
Advertising the Studio (May).

MOUNTS AND MOUNTING.

The style of mounting at present in fashion is so simple that it might at first seem as if nothing could be said on the subject. All that is apparently necessary is to get a piece of stout brown paper and dry-mount the print upon it. This, however, is not quite the case, as to get the best effect out of any print it must have a suitable setting, and to provide this is not so easy a matter as it might appear. There has been, I know, considerable difficulty in procuring suitable papers and cards during the war, but as these are produced in both England and America, it is to be hoped that we shall soon have a full range of tints and surfaces to choose from.

It does not seem to be generally appreciated that the appearance and tone-value of a print are greatly affected by the mount upon which it is placed, or else we should not see so many sepia-toned prints upon brown mounts, which nearly match their general tint, and hardly show where the print ends and the mount begins, thus causing a general flatness of

effect which is far from pleasing. It is, fortunately, impossible to reduce mounting to a system and to give rules for the choice of colours, but there are one or two points upon which most successful workers are agreed. One is that the depth (not colour) of the mount should never be as dark as the deepest tone in the print nor lighter than the highest light. Between these two limits there is a wide range to choose from, and even in everyday portraiture the general appearance of the work may be greatly improved by keeping this in mind. If we have only two mounting papers in stock, a cream and a rather dark brown, it is easy to see how much better some prints will look upon one than upon the other, and if we indulge in a combination of the two, one being used as a tint showing a narrow margin, we have an additional means of improving the effect. Some mounting papers have a different colour or depth on each side, so that it is possible to get tint and mount out of the same sheet. A good effect, and

one I am rather partial to, is to print with a narrow margin, so that the print is kept from running into the mount, and can be placed upon almost any suitable colour. The margin being exactly the same colour as the highest light of the print, cannot clash with it, nor with the mount itself. A trained eye will guide you to do the same thing with other colours, and the photographer who takes a pride in his work cannot do better than to procure a number of tints and mounts in various shades of brown, buff, cream, grey (not blue grey), and spend a spare hour or two in trying combinations of them with various classes of print. I hope that all the stocks of mounts with embossed coloured borders are used up, and that they will not be revived after the war. If we are to have any fancy work, let it be confined to folders, as these can be thrown away if the customer does not like them. For cheap work ornate mounts will probably always be popular, but for anything which is intended to be artistic they are as much out of place as a heavy signature embossed in gold has been found to be. Plate-marked mounts had a long run, but they, too, have died the death; photographs are not printed from copper-plates, and a good photograph does not need any such false pretences to help it out.

Trimming plays an important part in the artistic mounting of a picture, and for this reason I am glad that most photographers have abandoned the use of "stock" mounts. No matter how careful one may be in posing or in placing the figure on the plate, there are occasions when the necessity for cutting a picture to fixed dimensions will be detrimental. When long panel pictures were in vogue it was frequently necessary to cut off a portion of the clothes so as not to exceed the prescribed limits, but now so long as the picture is approximately the size paid for nobody will complain. It may be pointed out that in many cases judicious trimming will help the composition, bad balance being improved by cutting away unoccupied space at the side of the figure and making the edge serve as a support.

It is obvious that for trimming of this class the old style of cutting shape is inadequate, and those who prefer to use the knife will find that one glass of large size with cross lines ruled on the under side will be more convenient and will answer for all sizes, as two edges can first be cut and the print turned and squared up by placing the two edges against the nearest two lines and cutting the remaining sides. Obviously it is not necessary that the cut sides should touch the lines so long as they are parallel with them.

The most convenient way of cutting prints is to use a Merrett trimmer. With this it is easy to get perfectly square corners and to repeat any given size by laying the print accurately by the rule at the side. The only precautions necessary are to see that the print touches the rule throughout its whole length and to press firmly on the print while cutting. If the print slips, the corners will be out of truth. If at any time the trimmer be suspected of being out of adjustment, it may be tested by folding a piece of foolscap paper so as to give a sharp edge at the fold. Place this accurately to the rule and make a cut. When the paper is opened the edge should be quite straight across the sheet. If it be higher or lower in the middle the rule requires adjustment. This type of trimmer should not be used for heavy mounting papers or cardboard. For these a lever cutter should be used, and one fitted with a reliable clamp should be chosen. These cutters may also be used for prints, but require more care to get true rectangles. Some of the smaller sizes are unprovided with clamps, and when using these it is a good plan to press the print down with a glass cutting shape. This prevents the print from buckling and springing away from the blade.

Ovals and circles are best cut with the aid of zinc or brass shapes and a swivelled wheel cutter, a zinc plate being used to

support the print. Many people find difficulty in using this simple appliance, due usually to a lack of confidence. The cutter must be kept perfectly upright and pressed firmly against the edge of the guide. Practice upon a few waste prints will soon give the necessary touch. The zinc plate should be kept quite smooth, or the prints will have ragged edges. An occasional rub with emery paper will do all that is necessary. For odd sizes in circles I have found the Waterhouse diaphragms of a large lens very useful. The edges of the shapes must be kept free from notches, or the cutter will have a tendency to run into the print; but this is easily avoided by rubbing the notches with the emery paper.

A mount-cutter's knife is a most useful tool, both for trimming prints and cutting card; with a little practice it can be used for bevelling sketch portraits, making cut-out mounts, masks, and many other purposes. It is best to cut upon a glass plate for paper, as a cleaner edge is thus obtained. The edge of a good knife will not turn upon glass, nor will the glass be scratched. Nearly all mounting, at least in the smaller sizes, is done by the dry method, which gives a good finish, obviating the necessity for rolling, and avoiding cockling even upon the thinnest mounting papers. The following points must be observed to ensure success:—Both print and mount must be quite dry, or the print will stick to the plate, or at least show shiny patches where the damp places are. The heat must be adjusted to suit the tissue in use, and tissue requiring a high temperature should be avoided. During the war some very poor stuff was on the market and almost drove some people back to wet mounting. When cutting prints they must always be kept face upwards. When there is a narrow strip to be taken off, it is easier to see the width of this if the print is cut face downwards; but if this be done a line of shellac will show round the edge of the print. If any of this gets upon the plate the next print will probably stick to it. Prints may be tacked on to mounts very neatly by using a narrow strip of tissue at the top edge of the print. This should be cut a little shorter than the edge, so that the print will not have to be trimmed after attaching it.

Wet mounting is so well known that no detailed instructions are necessary except upon points where the beginner is likely to go wrong. The ready-made dextrine mountants of the Tixit type are the most convenient to use, and have the advantage that prints may be unmounted at any time by damping between wet blotting paper, but properly made starch is as good, and just now much cheaper. Few people make good starch paste, but it is easy if done as follows:—Mix the powder into a thick cream with cold water and see that any lumps are broken up; pour on absolutely boiling water, stirring all the time, until the paste goes clear and thickens; stir for a few moments longer and set aside to cool. Do not use until quite cold. Remove the top skin and take some of the paste into a small basin or saucer, so that it may be well broken up with the brush before spreading. Prints to be wet-mounted should be soaked in water till limp, then taken out singly and laid in a pile on a sheet of glass. This should be stood on edge and allowed to drain well, after which any surplus should be pressed out with a dry towel. Paste the top print, lift one corner with the point of a knife, and pick up the print with the thumb and finger of the left hand, taking care not to take hold near the edge; take the other corner with the right thumb and finger and place the print in the correct position on the mount. If not quite straight, put the tips of the fingers firmly on the face of the print and slide it into position. Rub down with a soft, damp sponge or a sheet of dry, clean paper. Hang up until the surface is fairly dry, but do not let the cards curl; pile the prints up together and put under a weight until quite dry. If a mounted print dries flat it will not curl afterwards; but if allowed to curl in drying.

nothing will flatten it permanently again. While on the subject of curling I may point out that only platinum prints and those upon plain salted paper—that is, without a gelatine or collodion coating—should be “backed on” to a mount by the top corners only, as emulsion papers, although quite flat at first, are liable to curl with every change in the atmosphere.

Passe-partout mounting is a convenient way of preserving prints which it is not desired to frame. It consists of binding up a mounted print with a sheet of glass in front, with or without the addition of a cardboard back, to which rings for hanging or a strut back can be attached. Ready-prepared binding paper, which only requires damping, may be purchased in rolls, and furnishes the most convenient way of working; but any stout paper or bookbinder's cloth may be used. The proper way to bind is to cut the four strips to fit the front glass, and to attach them very carefully upon the face, then turn the glass face down, lay the mounted print and back (if any) upon it, re-damp the adhesive on strips, turn them down on to the back, and rub well together. You will thus ensure a perfectly square and true edge on the front of the glass; the back does not matter.

Prints have sometimes to be mounted in optical contact with glass. This can easily be done by making a solution of clear gelatine, one ounce in a pint of water. This is poured while warm into a dish which will easily take the glass. The glass is then immersed, and when it has reached the temperature of the gelatine, is followed by the print face downwards: the two are withdrawn together and contact obtained by means of a flat squeegee. When quite dry, the face of the glass can be cleaned from any smears of gelatine. During the whole operation the gelatine solution must be kept warm and quite fluid. If there is any tendency to set while in use, it is useless.

I have sometimes had to mount prints upon wooden panels, and for this I apply fish-glue to the back of the dry print, using rather a stiff brush. The only points to observe are that the margins are well coated with glue and that any bubbles are carefully rubbed out. Bromide prints so treated may be varnished without further preparation. Engravings or platinotypes require careful sizing with a gelatine solution to prevent the varnish from penetrating the surface.

PRACTICUS.

SOME TESTS OF THE ACTION OF A SHUTTER OF THE FOCAL-PLANE TYPE.

[In a recent issue of the “Bulletin of the French Photographic Society” MM. M. Equer and E. Cousin, the latter the secretary of the Society, described some interesting experiments made by them in determining the difference of exposure given by a slit travelling close in front of the plate according to the stage in its journey across the sensitive surface. The experiments were made, not with a flexible blind wound from and to a roller, but with a rigid shutter with a fixed slit in it. It will be seen that the authors discover considerable variations in the exposure, and while they do not particularly describe the mechanism of their sliding plate, they express the opinion that the difference would be greater still in the case of a flexible blind, which is unrolled from one spindle and rolled upon another.—Eds. “B. J.”]

The ingenious method of measuring the speed of instantaneous shutters by means of “singing flames,” which was worked out some few years ago by M. Benoist, has been considerably used as a very simple and exact means of measuring the actual speeds of shutters. The results obtained have shown the usefulness of the method for lens shutters.

The same method may be employed equally well for the measurement of the speed of focal-plane shutters. Experiments in this application have been made in the laboratory of the French Photographic Society, and have prompted the observations which are the subject of the present communication.

In the camera which was tested the slit is contained in a sliding plate which is moved by a spring. By altering the tension of the spring the speed of movement of the sliding plate can be varied. The camera has a winding key and twelve notches corresponding with tensions from the lowest to the highest of the spring. The width of the slit may be altered, but has been kept at a single constant width for all the tests described below. It is plain that the times of exposure are proportional to the widths of the slit. There was no purpose, therefore, in making measurements for other widths of slit. The exposures are a matter of calculation so long as the slit is not so greatly narrowed as to give rise to diffraction phenomena. The only variable element in the tests is the tension of the spring.

The camera can be placed for use with the slit either horizontal or vertical. In the former case the slit-plate slides from top to bottom along a vertical path. In other words, it falls; and as it has an appreciable mass, the action of gravity is added to the action of the slit and the speed is increased. In the other position, at right-angles to the first, the plate slides from right to left along a horizontal path, the slit being vertical. Here gravity does not affect its action, or,

at any rate, has no further effect than increasing the friction and thus corresponding with a retarding action, if any.

The speeds are, therefore, different for a given tension of spring in the two positions, and hence the necessity of making two series of tests, one with the slit horizontal and the other with the slit vertical.

The fact that the slit-plate has a definite mass involves another result. At the moment of release the slit-plate starts from rest: its mass opposes the property of inertia to its movement—that is to say, its action is the one familiar in mechanics as starting resistance. Let it be supposed that the slit-plate has begun to move: its speed goes on increasing and would increase proportionally to the time if the motive force remained constant up to the moment when the slit-plate, having traversed its course, is arrested by the stops. But, in fact, the conditions of variation of the speed are complex. On the one hand the spring relaxes during the operation, and thus the motive power is not constant. On the other hand the constructor is at pains to provide opposite spring mechanisms for the purpose of regulating this acceleration; but when every precaution has been taken the compensation is incomplete. Thus, in the camera tested—and it is one of the highest reputation for the perfection of its construction—the different parts of the plate are unequally exposed: the time of exposure for the side of the plate corresponding with the departure of the slit-plate is appreciably greater than that of the part of the plate over which the slit-plate first passes. In ordinary practice this difference is not of great importance, but it is exhibited in a marked manner when the illumination of the subject photographed is uniform and when the exposure is on the underside. The image then shows, as a whole, an appearance of gradation in the direction corresponding to the movement of the slit.

When the position of the apparatus is such that the slit-plate slides from above to below the least exposed side of the plate is the lower edge. In the case of a landscape, this part is the sky, and thus a relatively shorter exposure is quite in place: the defect is converted into an advantage. However that may be, it is seen that if it is wished to ascertain exactly the speed of a focal-plane shutter it will not do to measure this speed anywhere on the plate. The results will be very different according to the position which the image of the singing flame occupies on the plate. Thus the plan is adopted of measuring the speed at the beginning, middle, and ends of the movement of the slit-plate. If three singing flames are used, this result is obtained by arranging them so that their images are projected one on the edge of the plate first uncovered by the slit, the next in the middle, and the third on the edge of the plate at which the slit passes off. Fortunately, it is possible to dispense with three separate flames and to use a single one, two other images of which are obtained by means of suitably placed mirrors. The tests were made under these conditions.

In the case of lens shutters, in order to separate the successive images of the singing flame, the camera was moved in any convenient plane. There was no need to concern oneself with the position of the axis around which rotation was made. Not so with a focal-plane shutter: in this case the line described on the plate by the successive images of the flame must be parallel with the edges of the slit. This is a necessary condition. If the line of the flames are oblique, the results are inaccurate: in place of the real speed one would measure a greater or lesser speed according to the direction of the inclination. There would be measured, in fact, a speed which would correspond to another width of slit or to another speed of the slit-plate.

The question arises—has this theoretical consideration any practical effect? A simple case may be taken: Suppose the slit was vertical and that rotation was done, as usual in tests of lens-shutters, around a vertical axis. Instead of being parallel, the line of the flames and the edges of the slit would be at right-angles, and the line of the flames would be impressed upon the sensitive plate in the direction of displacement of the slit. Thus the slit would follow the successive images of the flame. If the two moving elements proceeded abreast at the same speed the flames would be impressed throughout the whole width of the plate, and the result would be as though one had used an open lens without a shutter at all. If the two moving elements, moving always at the same speed instead of being abreast, are one behind the other, no image of the flames will be impressed on the plate, and the result will be as though the shutter had not been opened. In both cases it is plain that there is a great error. The error will be great if the speeds of the two moving elements, instead of being equal, are only of the same order of size. The question is—can it be so in practice. It is easy to show that it can, if we consider that the speeds in practice of the two moving elements are both of the order of size of about 1 metre per second. For a singing flame of frequency of 1/500th of a second the speed of movement of 1 metre per second on the plate for the successive images of the flame corresponds with a difference of 2 mm. between the axes of the images, since $0.002 \text{ m.} \times 500 = 1 \text{ metre}$. For a slit of 0.01 m. width the speed of 1 metre per second corresponds with an exposure of one-hundredth of a second, since $0.01 \text{ m.} \times 100 = 1 \text{ metre}$. Rotation should, therefore, be made around a vertical axis when the slit is horizontal, and around a horizontal axis when the slit is vertical.

Here it may be well to interpolate a note on the condition of parallelism between the path of the image of the flame and the edges of the slit and on the error involved when this con-

dition is not observed. These can be set forth exactly as follows:—Let M N O P (Fig. 1) be the sensitive plate, A B and C D the two edges of the slit, and L the width A C of the slit. Let V,

Fig. 1.

in size and direction, be the speed of the slit. The speed of the shutter is then the time of exposure of a point p of the plate. This time T is the time which elapses between the moment when the edge C D uncovers the point p and the moment when the edge A B covers it up again—that is to say, the time which the slit takes in order to displace itself through the distance L, so that the edge A B comes into the position C' D and the edge C' D into that of C' D'. We then have—

$$T = \frac{L}{V}$$

Now, on the other hand, let a, b, c, d, e, f, g, h, i, j, k, l, m, be the successive positions of the images of the singing flame, impressed or not impressed on the plate. Let V₁ in size and direction be the speed of movement, which is assumed to be uniform, of these images along their oblique path. Lastly, let v, in size and direction be the component of V₁ along a path parallel to V. If we assume now that the edge C D, just behind the moving image, overtakes it and uncovers it at g, the image g is the first which can impress itself on the plate. The images h and i are next impressed. At the instant when the slit will have been moved through the space L we shall have reached the end of the time T which is to be found. Now during this time the moving image will itself have moved so that the edge A B, arrived at C D, just does not cover it, hence the error. The other images j, k, are just about to impress themselves up to the instant when the edge A B, arrived at A' B', shall have rejoined and again covered the image of the flame. Thus, what we measure, when counting the number of the images is not the time T of exposure of a given point of the plate, but the time T₁ during which the images of the flame have impressed themselves.

Now the relative speed of the slit, relative, that is, to the moving image, is V-v, so that—

$$T_1 = \frac{L}{V-v}$$

The error T - T₁ = E can, therefore, be expressed as—

$$E = \frac{L}{V-v} - \frac{L}{V} = L \frac{v}{V(V-v)}$$

In order that the error shall be zero, v should disappear. Thus the speed V₁ should not have a component parallel to V, which is the same thing as saying that the path of the moving image should be parallel to the edges of the slit.

On the other hand, it is clear that—

$$\text{When } v = V, \frac{T_1}{T} = \text{infinity.}$$

The error is then such that the test gives the same result as though there were no shutter.

When $v = V/2$, then $\frac{T_1}{T} = 2$.

The error is then such that the results are twice what they should be.

When $v = \frac{V}{100}$, $\frac{T_1}{T} = \frac{100}{99}$,

and the error is then not more than 1 per cent. It will thus be seen that in practice approximate parallelism is quite sufficient.

Coming now to the test in which the slit was horizontal, the apparatus was fixed on a horizontal platform movable round a vertical axis. The height of the platform was adjusted so that the direct image of the singing flame came half-way up the plate. The two mirrors were placed, one above and the other below the flame at angles such that the two reflecting images of the flame were projected one on the upper edge and the other on the lower edge of the sensitive plate. In each test there was thus obtained at a single operation on the plate three lines of horizontal flame. The tests were made in succession for each of the twelve degrees of spring-tension corresponding with the setting of the notched winder. The results are shown in the following table:—

TABLE I.—HORIZONTAL SLIT.
Speeds measured.

Speed marked on the camera.	At upper edge of plate.	At middle of plate.	At lower edge of plate.
1/40	1/49	1/63	1/95
1/60	1/61	1/69	1/115
1/80	1/61	1/87	1/130
1/100	1/72	1/104	1/130
1/130	1/74	1/104	1/130
1/160	1/87	1/130	1/140
1/180	1/87	1/162	1/173
1/200	1/100	1/162	1/173
1/220	1/104	1/162	1/226
1/230	1/104	1/167	1/236
1/240	1/121	1/167	1/236
1/250	1/127	1/173	1/248

In making the tests with the slit in a vertical position the camera was fixed on a platform movable around a horizontal axis. The platform was placed so that the direct image of the flame was formed halfway along the width of the plate. The two mirrors were placed one to the right and the other to the left of the flame in position such that the two reflected images of the flame were formed one on the right-hand edge and the other on the left-hand edge of the plate. The negative thus showed three lines of vertical flame. In this case a special precaution was necessary. The singing flame is thin and long, and may be likened to a small vertical rod. When the line of the flames is horizontal the images of the small rods, more or less deformed by movement, are so separated that it is easy to count them. But when the line of flames is a vertical one, as in the present instance, the images of the rods tend to overlap and can no longer be counted. The practical means of overcoming this difficulty consists in surrounding the tube of the singing flame with two superposed envelopes of opaque paper, between which a space is contrived forming a circular slit of from 1 to 2 mm. diameter. The envelopes can be adjusted on the tube, so that the slit comes on a level with the flame and the length of the flame can thus be reduced to any required dimension necessary for avoiding overlapping of the images. The results obtained were as follows:—

TABLE II.—VERTICAL SLIT.

Speeds marked on camera.	At right-hand edge of plate.	At mid position of plate.	At left-hand edge of plate.
1/60	1/37	1/23	1/52
1/80	1/49	1/41	1/65
1/100	1/58	1/58	1/89
1/130	1/58	1/80	1/114
1/160	1/74	1/104	1/130
1/180	1/74	1/104	1/130
1/200	1/74	1/116	1/149
1/220	1/90	1/130	1/149
1/230	1/90	1/130	1/174
1/240	1/95	1/137	1/174
1/250	1/104	1/173	1/236

The diagram Fig. 2 is a reproduction of one of the test negatives, namely, that corresponding with the position of the vertical slit for the speed marked on the camera as 1/220th. It will be seen that the three lines of the flames corresponding respectively with the right-hand, mid-way, and left-hand por-

Fig. 2.

tions record, in the first case, six flame images, one partly exposed, the second four fully exposed, and the third four, of which one is partly exposed. (In reproducing the diagram from our French contemporary it may unfortunately happen that this minute difference will not be clearly shown in the printed reproduction.—Eds. "B.J.") The right-hand edge thus receives an exposure of 1/90th secs., the mid-way portion one of 1/130th secs., and the left-hand edge an exposure of 1/149th secs., the singing flame having a frequency of 520 vibrations per second.

Summarising the results of the tests, gravity exerts a different action according as the camera is held vertically or horizontally. The horizontal slit falls vertically, but the vertical slit slides laterally. For this reason a series of tests is necessary for each of the two positions.

Moreover, in consequence of the starting resistance and the acceleration of movement of the slit, the different parts of the plate are unequally exposed. It is, therefore, necessary to measure the time of exposure at the edge of the plate which the slit first reaches, at the middle of the plate, and at the edge which the slit last uncovers on leaving the plate. The three measurements can be made at a single operation by means of one flame, two supplementary images of which are formed by mirrors.

The direction of the axis around which the camera is turned in order to separate the images of the flame is of importance: this axis should be vertical when the slit is horizontal, and vice versa.

Also, when the axis is horizontal, overlapping of the images of the flame is prevented by reducing their length by surrounding the flame with an annular diaphragm.

The measurements show that in the camera tested:—

1. The speeds are very different, other things being equal, according as the apparatus is held one way or the other, especially when the spring tension is small. The effect of gravity is also proportionately greater as the spring tension is diminished.

2. The variation in the exposures obtained at opposite edges of the plate varies considerably—as much as in the ratio 1 : 2.

The tests refer to a shutter the slit of which is contained in a sliding plate. It would be of interest to make similar measurements on the speeds given by focal-plane shutters of the roller-blind type. The irregularities due to weight would be of a similar kind, but no doubt still more marked.

E. COUSIN.

A TABLE FOR P.O.P. TONING.

Messrs. RAJAB, LTD., have recently published the following table for the toning of P.O.P. on the system, first suggested, we think, by the Kodak Company, according to which a quantity of toning bath is measured out just sufficient for a certain number of prints, the bath being thrown away after use. Such a system is certainly one which goes a very long way to ensuring regularity of tone throughout a number of prints.

No. of Prints.			Water.	Ammonium Sulphocyanide 150 grs. in 15 oz. Water.	Gold Chloride 15 grains in 15 ozs. Water.
½ pl.	¼ pl.	1/1 pl.			
4	2	1	1 oz.	1 drm.	1 drm.
8	4	2	2 ..	2 ..	2 ..
12	6	3	3 ..	3 ..	3 ..
16	8	4	4 ..	4 ..	4 ..
20	10	5	5 ..	5 ..	5 ..
24	12	6	6 ..	6 ..	6 ..
28	14	7	7 ..	7 ..	7 ..
32	16	8	8 ..	8 ..	8 ..
36	18	9	9 ..	9 ..	9 ..
40	20	10	10 ..	10 ..	10 ..
44	22	11	11 ..	11 ..	11 ..
48	24	12	12 ..	12 ..	12 ..
64	32	16	16 ..	16 ..	16 ..

The simple rule to observe in compounding a toning bath:—Equal parts of each solution are taken, and for as many drachms of one of them, the same number of ounces of water must be added.

BRITISH PHOTOGRAPHIC MATERIALS AND FOREIGN MARKETS.

Not being on the spot it is impossible to know what efforts the British manufacturers are making in regard to competing in the foreign markets, but naturally one feels convinced that business men are doing all that is necessary in preparation for the commercial war, for, with the knowledge that Germany, despite internal dissensions, is actively engaged and determined to flood the Continental markets with her products, it is most important to export as soon as the permission is given.

That there is, on the Continent, a rich harvest awaiting the makers of photographic material goes without saying, and Switzerland is one of the countries where British goods are highly appreciated. Unfortunately, during the past four years the British manufacturers have been off the Swiss markets, and this means that a considerable effort must be made. The German manufacturers have had the field practically to themselves. Ernst Lomberg, of Langenberg, has inundated the country with his plates, and has and will have a firm hold until the plates from England appear on the scene when, it is quite possible, the superior quality will tell. In this respect it may be well to mention that the plates which have had an enormous sale are those of ordinary speed, and especially made for rotary photogravure negatives and positives. There is a big field for this class of work; the sizes of plates usually employed are 13 x 18 cm., 18 x 24, 24 x 30, though 30 x 40 and even larger are in demand. Another size, 21 x 27 although not frequently used, is on the market.

Panchromatic plates for three-colour work are slowly becoming popular and may in time rival, or even oust, the emulsion which has had a long run of success. Lomberg, taking advantage of the opportunity that war had placed in his way, put forward a panchromatic plate for process work, but, from personal observation, it has not attained the high standard of perfection of the plates of English manufacture. But it is not only process and photogravure work that call for plates. Plates and films for outdoor photography have ready and appreciative customers. Bromide and other papers will meet with a steady sale. Certain British chemicals, although up against strong competition, stand every chance of competing favourably with foreign products, again, owing to their reputation and quality.

Two things which might materially assist the sale of British products would be a depot in one of the large towns where every article would be available, and, which is perhaps more important, a liberal distribution of attractive advertisements, such as are seen in the Almanac. These, exposed in the shops of photographic dealers, would not fail to attract attention.

Plates and papers should have full directions, formulæ and observations printed in English, French and German. This is done in many instances, but it is absolutely necessary, and its importance cannot be overestimated.

The graphic arts should find unlimited scope on the Continent. British picture-postcards are greatly appreciated, especially those of a humorous nature. Christmas and New Year cards as usual were "Printed in Germany." But goods that are made in England, or "Printed in England," are highly popular, and it behoves the British makers to remember this and to take every advantage. Besides, after having beaten the Hun in the field, it would be a glorious thing to drive him out of the markets of the world.

E. J. GLUMART.

Patent News.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

CINEMATOGRAPH SHUTTERS.—No. 114,994 (November 27, 1917).

The masking blade *a* of the shutter is made in the form of a skeleton frame covered with a sheet of dark blue or other coloured gelatine, mica, or the like, such sheet of gelatine having plane surfaces and being cemented to the skeleton frame. In

conjunction with the masking blade *a* is shown a flicker blade *b* of opaque material. This flicker blade is formed with radial openings or slots *c*. Any number of such slots may be used, nine being shown in the drawing as having been found very suitable. Alfred George Smith, 5, Winter Garden Terrace, Southport.

APPLICATIONS FOR REGISTRATION.

MERITOL.—No. 389,170. Photographic chemicals. Johnson and Sons, Manufacturing Chemists, Limited, 23, Cross Street, Finsbury, London, E.C., fine chemical manufacturers. March 12, 1919.

CATALOGUES AND TRADE NOTICES.

MESSRS. WAHLTUCH, SMITH, AND CO., LTD., 30, Chapel Street, Salford, Manchester, have just issued a leaflet describing a number of their specialities in equipment of professional photography. These include a universal printing cabinet, to which their "Pelican" strip printer can be adapted, the "Bram" vignette printing frame, sketch printer, and copying outfit. The list is one which represents much inventive capacity applied to labour-saving, and any professional photographer who has not received one may be advised to get one.

MESSRS. WALLACE HEATON, LTD., 17-19, Change Alley, Sheffield, send us their May catalogue of second-hand apparatus. It is a 48-page closely-printed list, describing a very great stock of cameras, lenses, and other apparatus. A feature of the list is its illustrations of the more popular models of hand and reflex cameras, but its many itemized bargains will attract the photographer who is on the look-out for equipment for the coming season. Messrs. Wallace Heaton offer to post the monthly issue of this list regularly to any photographer who will so apply.

TUESDAY, MAY 27.

Royal Photographic Society.—Technical Meeting. "Spiders: Their Structure and Habits." Dr. G. H. Rodman.
Hackney Photographic Society.—Annual Meeting.
Manchester Amateur Photographic Society.—"A Ramble Into Birdland."
Rev. E. C. Harris.
Chelsea Photographic Society.—"Pictorial Ideals." M. O. Dell.

WEDNESDAY, MAY 28.

Croydon Camera Club.—Members' Print Display.
Photomicrographic Society.—Annual General Meeting, Exhibition, etc.

THURSDAY, MAY 29.

Hampshire House Photographic Society.—"Developers and Development." G. C. Weston.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, May 20, Dr. Rodman in the chair.

Mr. E. W. Mellor delivered a lecture entitled "The Home of the Rajput," showing by a large series of altogether admirable lantern transparencies the country and customs of the well-known Indian race.

On the proposition of the Chairman the heartiest thanks of the large audience were accorded to the lecturer.

PROFESSIONAL PHOTOGRAPHERS ASSOCIATION.

A meeting of the Council was held on Friday, May 9th, 1919.

Present: Messrs. Gordon Chase, Corbett, Ellis, Fry, Gray, Haines, Lang-Sims, St. George, Speaight and Wakefield (London members); and Marcus Adams (Reading), T. Chadley (Chester), Illingworth (Northampton), Lankester (Tunbridge Wells) and Read (Southport).

The minutes of the previous meeting were read and confirmed. Letters were read expressing regret at inability to attend from Messrs. Spink (Brighton) and George Hana (London).

The Hon. Secretary reported:—

That he was in correspondence with the Hon. Secretary of the Institute of Ophthalmic Opticians in the matter of the consideration of possible future trade regulations which might affect their mutual interests. He also reported that twelve new members had

been enrolled since the last report, and that about thirty letters from members dealing with controversial and other matters had been dealt with by himself since the last meeting. Two of these were left over for the Council's consideration, viz., one from a member who requested advice in regard to the allowance of holidays with payment to assistants; and another suggesting that London photographers should be provided with a members meeting from time to time.

In regard to the holiday question, Mr. Speaight stated that his firm gave ordinary assistants one week's holiday each year with pay, heads of departments two weeks' holiday with pay. Mr. Haines mentioned that his firm gave one day (with pay) for each month of service to every assistant who had not served a complete year. After twelve months' service each received two weeks' holiday. Further opinion was substantially to the same intent and the Hon. Secretary was directed to confirm his reply to the inquiring member.

In regard to the London members' meeting it was pointed out that the meetings had been tried and had been abandoned for several reasons, each a small matter in itself, but cumulative in effect. Country members thought that London members had some advantage over them in the matter, and the Council felt that the energies of the officers were more usefully employed in attending to the purely business requirements of their large membership. There was a feeling on the part of some members of the Council, however, that the meetings should be tried again, and the Hon. Secretary was instructed to write the inquiring member accordingly.

A case of infringement of copyright was reported by the Hon. Secretary, and the Council endorsed the action already taken. The Hon. Treasurer placed the banker's pass book on the table; the Council authorised the payment of accounts amounting to £26.

Mr. Illingworth moved that the P.P.A. apply for a charter of incorporation, and offered arguments in support of his proposal. The first was that they would raise and establish their status. They would cease to be one of a thousand trade and business associations of which little or no notice is taken because there was nothing on the face of them to show that they were representative or of any standing. The fact that they were incorporated would carry with it a recognition of their standing as a body representing the practisers of the art of photography. As showing that incorporation is deemed of importance it was mentioned that all Chambers of Commerce of any notability were becoming incorporated, because Chambers of Commerce which were incorporated are brought into closer and more helpful relations with the Board of Trade. Then in all matters affecting their business and art on which it might become necessary or desirable to make their views known, they would, as an incorporated body, be more likely to get a hearing and be recognised as the official organ of the great business they carried on. As an incorporated association they would have the privileges of a limited company—could act as a legal body and do many things for the promotion of photography and the protection of one another, much more easily than a loose association. That this was recognised was seen by the powers under the Companies' Acts for the registration as incorporated bodies of associations for the promotion of art, science and commerce without the use of the word "limited;" but with the advantages of a limited liability company, the incorporated associations being limited by guarantee—that is, every member guarantees to pay his share of the debts and liabilities of the Association if it should be wound up during the time he was a member or within twelve months afterwards. This gave membership a more important and more stable character.

Mr. Illingworth continued that he was not a lawyer and could not explain the legal advantages which an incorporated association would have, but he understood there were many things, such as acquiring central offices, forming a club, carrying on experimental work. In fact, all the things which one could think of as being within the scope of a really vigorous association in the interests of their art and business could be done much more easily and effectively by an incorporated body than by an association which was a mere society, the powers, rights, liabilities and responsibilities of the members of the committee of which were often the subject of doubt and difficulty. That was why so many trades and pro-

lessons were taking advantage of incorporation. He urged that they should make a bold move to give dignity and importance and status to their association. At any rate, he felt there was quite enough of reason in his suggestion to make it worthy of consideration, and he should be quite satisfied if a special committee were appointed to explore the subject and report to the members. He could not but think that such a committee would report in favour of incorporation, but in any case the proposal would be carefully considered and canvassed from every point of view.

Mr. Haines seconded the resolution pro-forma, and to obtain a discussion. Mr. Illingworth in reply to a question thought the cost would be about £100. The President (Mr. St. George) thought the expense a secondary matter provided that some concrete advantages were obtained. After a discussion, and in order that the members might have a better opportunity of following Illingworth's statement, it was resolved that type-written copies of Mr. Illingworth's introductory remarks be circulated amongst members of the Council so that they can peruse them before the next meeting, and that the matter be placed on the Agenda for the next meeting.

Mr. Marcus Adams stated that he desired to ascertain the views of the Council upon the reports which he had submitted on assistants, and to ascertain if it was intended to proceed further.

Mr. Road said that his idea was that parents should know that boys who adopted the photographic profession as a business career had prospects of good appointments, and for their encouragement examinations should be held, and awards given for good work.

After discussion a committee consisting of Messrs. Adams, Haines, Lang-Sims, Speaight and Wakefield was appointed to go into the matter and, if possible, formulate and present a scheme to the Council, Mr. Marcus Adams to act as convener.

Mr. Marcus Adams further suggested the appointment of a committee to consider the most suitable arrangements for a future secretariat. After discussion, provision was made for the engagement of such clerical assistance as would prove necessary to carry on the work of the Association.

The Hon. Secretary passed round copies of an official explanation of the Whitley Report, and was instructed to send copies to all members of the Council not present.

The Hon. Secretary reported that a new edition of the Handbook, revised, and with added information, was in course of preparation, and when completed would be issued to all members.

Mr. Wakefield reported the result of his interview with the Secretary of a London trade association at whose premises, centrally situate, the P.P.A. could have a London office. Such an office was available. It was resolved that a committee to consist of the President and Messrs. Haines and Wakefield should interview the Secretary of the trade association and report to the Council.

CROYDON CAMERA CLUB

Last week a display was held of prints from negatives taken at the Easter outing. The exhibits were few and the award was withheld. A masterpiece by Mr. J. Keane revealed a member supported by a signpost outside the halfway house. The upright furnished by the post, in combination with the inclined line of the figure, according to Mr. Brigham Young, is the ideal composition for giving a sense of stability to the picture. Another lettering convention blown to pieces.

Mr. Cavendish Morton criticised the exhibits in a very hopeful way, but put his foot in it badly by inadvertently falling foul of Mr. Harpur's pet method of introducing art by tulle on the lens. Being admonished by the indignant pictorialist, the critic mildly pointed out that if inferior artists, such as Whistler, could achieve the results they did without employing tulle, it was open to Mr. Harpur to do the same.

It may be added that a part of the evening was devoted to an exchange of opinions on the previous week's lecture on "Psychic Photography," and it now occurs to the reporter that notwithstanding the subject is taboo in these columns, without breaking it, several references might have been made to a remarkable fixture.

Well to repair the omission, the lecturer turned out to be a down-

right plucky old gentleman, and it must be admitted he got it rather hot—on reflection too hot in fact, even if many grew strongly antagonistic. On the other hand if he had been young it may be confidently said a red-hot poker would have been cool to sit upon. Again, he was very well able to take care of himself—for example, such a retort as "One fool at a time, gentlemen," even if it did not display great originality, at least indicated a robust spirit, and a nice sense of locality.

Mr. W. F. Slater and other Kodak representatives, with several outside photographic experts, were present, and an exquisite if puzzling touch was afforded by the lecturer when he, more than once, alluded to the "church of Slater." Possibly merely slips of the tongue, and Mr. Slater, on being subsequently approached, energetically denied being an archbishop in disguise, or anything appertaining to the cleric. But you never can tell, and members of the South London Society will be on the safe side if they in future address him as "Reverend." Frequent references were also made to Messrs. Kodak as being responsible for combination psychic prints, and if the audience had been non-photographic an impression might have been created that this firm were also in the business. Of course, it is not suggested any such intent existed.

As the evening wore on the dear old gentleman painfully realised the barren nature of the Croydon soil, but hope appeared on his countenance when at the end Mr. Harpur said he had been much interested, having personally experienced an astonishing manifestation in psychic photography. Undeterred by a vision of an editorial blasphemy hovering in the air, we proceed to tell the tale. It transpired that Mr. Harpur was entrusted by a friend with six plates to develop which had been exposed during a séance. The expert took them into his dark-room, and four plates received the usual treatment, but nothing appeared, and then a loud crashing sound sent him flying panic-stricken into daylight. Summoning up his courage, he re-entered the dark-room and found some bricks had fallen down the chimney. "I then developed the remaining two plates with the same result," he concluded with an air indicating that an important advance in knowledge had been imparted. "I don't see any point in your tale at all," tartly said the naturally disappointed lecturer.

During the evening a letter was read from Mr. Nevil Muskelyne, also some letters from the lecturer, written more in sorrow than in anger. It was comforting to learn that he intended letting his experiences at Croydon pass from the mind as an unpleasant dream.

In last week's report his name was, by a printer's slip, given as "Wates" instead of "Carter."

Commercial & Legal Intelligence.

LEGAL NOTICES. A first and final dividend of 3s. 3d. in the £ has been declared in the failure of Frederick William Gray, and Margaret Jane Gray, photographers, carrying on business at 11, Queen Victoria Street, Leeds, under the style of the Empire Studios. In the separate estate of Margaret Jane Gray, a first and final dividend of 20s. in the £ has been declared. The dividends are payable on May 21 at the office of Mr. G. H. L. Volans, Incorporated Accountant, 2, Albion Place, Leeds.

Notice is given of the dissolution of the partnership between Harry Hall and Frank Siggers, carrying on business as photographers, under the style of Hall and Siggers. All debts due to and owing by the late firm will be received and paid by Harry Hall.

NEW COMPANIES.

F. BRODRICK, LTD.—This private company was registered on May 9, with a capital of £1,000 in £1 shares. Objects: To enter into an agreement with F. Brodrick and to carry on the business of manufacturers of and dealers in photographic and cinematograph apparatus. The subscribers (each with one share) are:—F. Brodrick, 20, Heathfield Gardens, Chiswick, W., photo apparatus manufacturer; Mrs. G. H. Brodrick, 37, Heathfield Gardens, Chiswick, W. Directors: F. Brodrick, Mrs. G. H. Brodrick and C. B. Smith. Registered office: 50, High Street, Bloomsbury, W.C.

ADAMS STUDIOS, LTD.—This private company was registered on

May 7 with a capital of £3,000 in £1 shares. Objects as title. The subscribers are:—B. Park, 117, Adelaide Road, Hampstead, 600 shares; M. Adams, 83, Whiteknights Road, Earley, Reading, 900 shares. Permanent directors:—B. Park and M. Adams. Solicitors: Carpenter and Wilson, 4, Trafalgar Square, W.C.2.

FULTON PROCESS (1919), LTD.—This private company was registered on May 9 with a capital of £2,000 in £1 shares. Objects: To develop the Fulton Process in all its applications and to manufacture photographs, pictures, illuminated and other signs, theatrical scenery, etc. The subscribers (each with one share) are: A. A. Simco, 1, Bensfield Road, New Cross, S.E.14, scenic artist; G. Wilkinson, 24, Caithness Road, West Kensington, W.14, scenic artist. Directors: A. A. Simco and G. Wilkinson. Registered office: 25, Caithness Road, W.

GENERAL CHEMICAL AND PHARMACEUTICAL CO., LTD.—This private company was registered on May 10 with a capital of £6,000 in £1 shares (3,000 preference). Objects: Manufacturers of and dealers in chemical and other preparations, photographic requisites, etc. First directors: R. S. Haskew, 103, Hampton Road, E.7, technical and research chemist; G. A. Bellwood, Bishop Norton, Lincs, yeoman. R. S. Haskew is permanent.

News and Notes.

FIRE AT A STUDIO.—In reference to the report which appeared in last week's issue of a fire at the premises of Messrs. Bayley's Studios, Ltd., 16, Tottenham Court Road, W., we are informed that the report was very greatly in error. We are glad to learn from Messrs. Bayley's Studios, Ltd., that the fire was not, as stated, serious; that it was in fact so slight that within a very short time of the outbreak having taken place the workroom was again being used for its customary purposes. Moreover, Messrs. Bayley's Studios, Ltd., state that the fire originated not through a carelessly thrown down light, but from a source outside the premises occupied by them. We cannot sufficiently regret that any misleading statements should have found a place in the report of the occurrence, and are exceedingly sorry if they have created any wrong impression of the conditions prevailing in the establishment of Messrs. Bayley's Studios, Ltd.

MESRS. WAHLTUCH, SMITH, AND Co. inform us that Mr. Albert Houghton has joined their travelling staff, and will begin his representation of them in the Midlands and South as from Saturday next, May 24.

AERIAL PHOTOGRAPHY.—The Royal Photographic Society announces that at the last of the meetings to be held during the present session—namely, that on June 3—a paper on aerial photography will be read by Major F. C. V. Laws, of the Photographic Section, Royal Air Force.

MR. GEORGE HANA, the well-known theatrical photographer of Bedford Street and ex-President of the P.P.A., underwent a serious operation some ten days ago. We are quite sure that his many friends will share our own pleasure that it has proved very successful and that Mr. Hana, cheerful as ever, is hopeful of quickly being himself again.

PHOTO-MICROGRAPHIC SOCIETY.—The annual general meeting will be held on Wednesday, May 28, at 7 p.m., at King's College Laboratories, 62, Chandos Street, W.C., when there will be an exhibition of members' work, etc. Cards of invitation may be obtained on application to the hon. secretary, Mr. J. G. Bradbury, 1, Hogarth Hill, Finchley Road, Hendon, London, N.W.4.

TO NEWCASTLE PHOTOGRAPHERS.—A proposal has been made for the establishment of increased co-operation among photographers in Newcastle, and the initiation of a club or society for the purpose. Those interested, and desirous of combining their photographic activities, are invited to communicate with Mr. J. Nicol, at the de Bear Schools, Limited, Dial House, Northumberland Street, who would be able to provide premises and a dark room should a sufficient number come forward.

THE TORONTO CAMERA CLUB.—The Toronto Camera Club will hold its twenty-eighth annual exhibition at the Canadian National Exhibition, which opens on August 25 next and closes on September 6. The committee hope to receive a large representation of English pictorial work. Prints must be mounted but not framed, and should be sent by post to reach the honorary secretary, Mr. A. S. Goss, Toronto Camera Club, 2, Gould Street, Toronto, Canada, by July 19 next. An entry fee of 50 cents is charged.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS' EXHIBITION AT BLACKPOOL.—The responses received by the hon. secretary have far exceeded the expectations of the committee, and it will be to the interest of every photographer within reasonable distance of Blackpool to visit this exhibition, which opens on Tuesday next, May 27, at the Art Gallery. The committee earnestly request the attendance of every member at the annual general meeting, which will be held at the Palatine Hotel, Blackpool, on May 27 at 2.30 p.m. prompt.

AFFILIATION OF PHOTOGRAPHIC SOCIETIES.—The annual outing will take place on Saturday, June 21. It is being organised by the Croydon Camera Club, and the route will be from Waddon, near West Croydon, along the River Wandle, through Carshalton Park, to Wallington, where tea will be provided. Medals are offered by the Croydon Camera Club (*whose members will be ineligible to compete*) as follows:—(a) For the best uncontrolled contact print; (b) For the best bromide enlargement; (c) For the best print by oil, Bromoil, gun-bichromate, or other "controlled" process; and (d) For the best lantern slide. The United Stereoscopic Society also offers a medal for the best stereogram. Special permissions for members of the Affiliation to photograph in the Whitgift Hospital, the Archbishop's Palace, and the old parish church in Croydon, and also in private grounds on the Wandle route, will be obtained.

THE MODEL HOMES EXHIBITION, organised by the "Daily Express," which opened at the Central Hall, Westminster, on Monday last and remains open until June 14, has as its keynote the saving of domestic labour. Plans and models of cottages are a prominent feature of the exhibition, and Mr. Pemberton Billing shows a full-size four-roomed house built with a newly invented stove of his at the centre, providing heat in all four rooms, as well as in bedrooms and bathroom overhead. Among the many labour-saving appliances there are some which have an interest for photographers, for example, those for the heating of water. The portable water-heaters of the well-known firms of Parkinson, Richmond, and the Davis Gas Stove Company are shown, as well as two others quite recently introduced. One of these latter is a very neat water-heater of the coil type made by the Martin Engineering Company, 49, Theobald's Road, Holborn, London, W.C.1. The water is turned on, then the gas, and warm or boiling water obtained within a few seconds. Another is the "Helios" heater of the Wembley Heating Company, Wembley, London, N.W., an appliance which keeps three gallons of water always at nearly boiling heat, and automatically turns on the gas as hot water is drawn off. A space-saving device which may have its appeal to photographers having small workrooms is a table which, in the closed position, rests on a cupboard, but is readily drawn forward to provide a working surface formed by the cupboard and table tops which are caused to lie perfectly flush with each other. This is the S.O.S. table of Mr. L. Cancellor, of 301, West End Lane, N.W.6.

QUININE BACKING FOR PLATES.—A note in the "Pharmaceutical Journal," by Mr. F. J. Yeatman, is as follows:—In photographing a church interior, requiring a long exposure, the author was confronted with the usual difficulty of halation, and in the absence of backed plates or the ordinary backing solutions, sought a means of overcoming it. Surmising that a minutely crystalline deposit, brought into optical contact with the glass of the plate (by application in the form of a solution in a volatile menstruum), would prevent the reflection of light from the inner surface contiguous to it, the following solution was prepared:—

Quinine hydrochloride	60 grains
Absolute alcohol	1 oz. fl.
Dilute sulphuric acid	3 drops

A plain glass was taken, and half its surface on one side was covered

with the solution by means of a tuft of cotton-wool. When dry (a matter of a few seconds) it was dabbed over lightly with the solution, and again allowed to dry. Holding this horizontally (deposit downwards) near a window, the window-frames could be seen, reflected, accompanied by a dim fringe, presumed to be a secondary reflection from the lower inner surface of the plate. This fringe ceased on the part of the plate covered by the solution. Photographic plates were then backed in this manner, and yielded successful halation-free photographs, though taken under severe test conditions. The church interior above alluded to was given half an hour's exposure, and no halation ensued. The back of the plate is, of course, easily cleaned after development or fixing by means of weak acid.

A WIRELESS PHOTOGRAPHIC RECEIVER.—We read in an American journal that wireless messages can be received and recorded at a greater speed and with greater accuracy by means of a new photographic device invented by Charles A. Hoxie, an engineer of the General Electric Company. It is stated to be in use at the present time by naval engineers at Otter Cliff, near Bar Harbour, Maine. The mechanism is based on comparatively simple electrical principles. A light mirror "flutters" in electro-magnetic tune with the minute electric impulses coming from the receiving antenna. The duration and extent of the mirror's oscillations vary according to the dot, dash, or silence of the sending station. This mirror reflects a beam of light on a moving photo-sensitive tape. The tape, propelled by an electric motor, moves up and down through vertical pipes which contain the developing and fixing chemicals. It is then washed in running water, and is dried by electric heat, assisted by forced draught. Like the tape from a tape machine, the message pours into a basket. In rapid receiving there is an average of one word for every inch of tape, and receiving operators can read the record at a speed of 50 to 100 words per minute. The apparatus in operation at Bar Harbour is said to have repeatedly recorded regular traffic schedules ranging from 1,000 to 7,000 words without interruption, and at a speed of 40 to 45 words per minute. It is used in supplement to the ordinary type of receiving set. At the same time that the message is photographically impressed upon the tape a fleeting visible image of the signals can be seen on the ground glass of the machine.

Correspondence.

- Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- We do not undertake responsibility for the opinions expressed by our correspondents.

REVERSAL IN TANK DEVELOPMENT.

To the Editors.

Gentlemen,—With reference to your correspondent Mr. Binns re the reversal in tank development, we should like to add our experiences. We develop daily hundreds of films for amateurs in the long vertical tanks, and do at times come across the remarkable result referred to in your column. Only last week we had a film nicely exposed vest-pocket Kodak size with seven negatives and one positive on it. The film was in no parts fogged nor in any way incorrectly handled, and the positive we had was as good and bright as any made with a lantern plate. It seems to us that it is the action of the light on the lens which reflects back. This is a very poor solution of the problem, but we cannot think of anything else.

As previously stated, the result is quite common on amateur films, and we should certainly like to see one of Mr. Binns' "positives" to see how they compare with the results we saw. If Mr. Binns remembers the exposure and treatment throughout, perhaps it might assist someone to solve the difficult problem which so far seems beyond hopes.—Yours faithfully,

A. DYMCK, Manager,
for Arthur J. C. Lewis.

New Barnet, Herts.

FORTHCOMING EXHIBITIONS.

September 13 to October 11.—London Salon of Photography. Entries close September 2. Hon. sec., 5a, Pall Mall East, London, 1

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

1. L.—We think no metal dish is immune from liability to give spots in hypo-dium toning, but we were recently told by a very large firm using this process that a tin dish is perfectly satisfactory. We mean solid tin, not tinned iron plate. We should view a lead coated steel dish with great suspicion.

G. F.—Our opinion is that the removal of a business from one address to another is not a new retail business within the meaning of the Order. If we were you we should not worry to apply for a licence. If the matter should come to the notice of the licence committee we should say you have a defence.

M. N.—Your description of the proposed business is not sufficient for us to say definitely. If you are dealing with the general public you require to obtain a licence, but if your transactions are wholly with those in a given trade or business it does not come within the Order requiring a licence for a new retail business.

H. B.—The "Cannier" and other cameras for street photography came for the most part from America and the importation is now prohibited. The two best firms for you to apply to are Messrs. J. Fallowfield, 146, Charing Cross Road, W.C.2, and Messrs. Billcliff's Camera Works, Richmond Street, Boundary Lane, Manchester.

B. O.—Cards with wordings you mention used to be stick articles with the larger professional dealers, such as Houghtons, Kodak, and the Tress Company, although very likely they have dropped out during the war. Any of these firms could get tickets written, or you could have them done by a firm of shop-fitters such as Messrs. Wm. Potter and Sons, Ltd., 160-161, Aldersgate Street, London, E.C.

G. N.—Assistants who come within the Shops Act and are employed in a place which is a holiday resort, in which place the weekly half-holiday is suspended, can demand a holiday on full pay of not less than two weeks, which we understand, must be one holiday of two consecutive weeks. There is nothing in the Act requiring a double rate of payment for the holiday period if the holiday is not taken.

M. N.—It is impossible for us to give you any precise figures, but, roughly speaking, we think that you should have a capital of about £2,000 to start in a good way and to keep going until the money begins to come in. Most people start in a more modest way and "cut their coat according to their cloth." It must be borne in mind that all building and decorating materials, apparatus, etc., are at very high rates just now, and that the munition boom is over.

G. D.—1. On the whole, the best is to paint with ordinary bath enamel, though it will not last very long. 2. If a little olive oil run round the junction of the cell and tube does not ease the former, the only thing is to send the lens to the maker, who can separate the two parts on a lathe. 3. The address of Messrs. Valentine and Sons is Dundee. 4. Photochrom, Ltd., 7, Old Bailey, London, E.C. 5. From the Quta Company, 252-256, Haydon Road, Wimbledon, S.W.

O. N.—Two to three seconds can hardly be considered a long exposure, especially if you want soft lighting. You can greatly reduce it by bringing the sitter nearer the light; a foot or two makes a great difference. You cannot get a better type of lens than the one you have, but the focal length is too short. Even for postcards, 8-in. is about the limit. The 2B Dallmeyer would be useful, as this works at $f/3$, and is about the right focal length for you. We do not know the current price new, but second-hand ones can be bought for from £5 upwards.

S. N.—The alternative if you must dispense with a lamp requiring hand adjustment, is one of the focus half-watt lamps probably now obtainable again from the General Electric Company, Ltd., 67, Queen Victoria Street, London, E.C. Very likely one of sufficient power (they are made in a series of powers) will be too big for your lantern body, but that you can ascertain from G.E.C. A power suitable for enlarging up to, say, 20 x 16 is about 1,000 c.p. The other course is to fit up an illuminating chamber in which the negative is lighted by a light reflected from the inside white walls. Messrs. Marion, 3, Soho Square, London, W.1, make an appliance of this kind which can be fitted with incandescent filament lamps of any required power. It is a very good system.

P. O. V.—1. On the average, unless the worker has much more than the ordinary skill, the results in development of different subjects together in a tank are better than by separate treatment in dishes. 2. Provided that exposures are reasonably correct, yes. With the necessary skill in development better results will be obtained from incorrect exposures by separate dish development, but in the absence of the knowledge of what to do with incorrect exposures, the batch system of development in such cases will give better results. 3. In the case of plates taken in a daylight studio, where exposure may be said to be reasonably correct, even if not exactly correct, the tank method certainly gives results which are as good, if not better, than those singly developed in dishes.

LIGHTING.—My studio is a temporary structure erected in my garden about three years ago and lit from the north. My next-door neighbour intends erecting a conservatory which will run parallel with studio and about two yards away. Will you kindly let me know if this will affect the lighting of my sitters in any way, and, if so, if I can by law prevent him building?—CONSTANT READER.

The conservatory will undoubtedly reduce your light, but the extent of this will depend upon the height. It may not be serious. You cannot do anything to prevent the erection of the conservatory unless your studio has been there twenty years. Try to arrange amicably, so that as little harm as possible is done.

R. F.—The address of an applicant for a patent is not ascertainable until the publication of his specification, which may be anything from six to eighteen months after the date of application. There have, however, been a fair number of specifications of patents for methods of stereo-cinematography published within the last few years. You will find these indexed in the annual index of the "B.J." under "cinematography, stereo." You can see these volumes in the library of the Patent Office, 25, Southampton Buildings, Chancery Lane, W.C., and in the same library you can also look up the actual patent specifications and ascertain from them the addresses of the patentees. This is the only suggestion we can make which appears to satisfy your requirements.

H. N.—Providing the generator receives the regular attention which is necessary the acetylene light is a very satisfactory one for enlarging and, of course, for bromide printing if the printer is of the type to take a flame light. Of the generators described in the catalogue we prefer the "Incanto," which is the manufacture of Thorne and Huddle, one of the oldest firms in the acetylene business. We have no data as to the cost of working: a great deal depends as to whether the generator is in constant use or is out of use for periods during which, even with the best generators, there is deterioration of the carbide. We believe carbide is now readily obtainable. You can ascertain this easily from any local dealer in motor requisites. The only alternative light is the "Luna" spirit mantle lamp of Messrs. W. C. Hughes and Co., 82, Mortimer Road, Kingsland, N.1, fairly suitable for enlarging, but

too powerful for bromide printing. If you can use neither gas nor electric current, we should think that a good central draught oil lamp is the best choice for the printer.

D. N.—Without knowing what your limit of size is, it is very difficult to plan such a dark-room as you suggest. Four feet by three by six high would seem the smallest size that could be worked in comfortably. This might be composed of two shallow boxes each four by three by nine inches deep. They could be kept apart by six jointed poles fitted into sockets in the boxes—one pole at each corner and two at the sides, so as to carry the sink securely. Opaque curtains fixed at top and bottom, except at one side where light flap would serve as door. For the enlarger a small conical bellows camera would be more portable and convenient than any shelf arrangement. Ventilation could be secured by trapped opening in the top and bottom. Such details as water supply, illumination, etc., you can doubtless fill in according to circumstances. You do not say in what climate you are going to work in. In a hot country you would probably find the above rather close. Do not entertain any idea of the old Wratten tent pattern. This was all right for collodion work, in which development only occupied a few seconds; for dry-plate and bromide work it would be unbearable.

G. A.—The pinholes are due either to dust of a particularly objectionable kind on the plates during exposure or to some grit on them during development. If the negatives were not so atrociously dense the pinholes would not be such a serious affair, and could be readily spotted out. But you ought not to get them if you are filtering the developer as you describe. Better try also boiling the water before making stock solutions of the developer and also boiling any water used for diluting them when making up the working developer. As regards a self-acting system of filtering, you can easily arrange this, or rather your local chemist can supply you with the apparatus in the shape of a twice-bent glass tube which serves as a syphon of water from any large vessel in which you have it, the flow of the water being controlled to the required degree of slowness for filtration by means of a rubber tube attached to it and more or less closed with a screw cap. Both of the negatives are horribly over-exposed. We should think you are using rapid plates, whereas you should have process or photo-mechanical plates in order to get satisfactory results in copying jobs of this kind.

SUMMARY

The "British Journal" for next week, June 6, will be a specially large issue, containing an additional number of articles and other features appropriate to the fact that an extra edition is posted by our publishers to photographers and others in all parts of the world.

In his article this week, "Practicus" deals with such general business methods in the carrying on of a photographic portrait business as can be the subject of definite advice. His recommendations are made chiefly in respect to the adoption of an efficient system of book keeping and to the advisable means which may be adopted for the collection of outstanding accounts. (P. 291.)

Mr. Spencer Leigh Hughes, M.P., formerly "Sub-Ran" of the "Morning Leader," has written a sketch of the introduction and development of photography in warfare, in the course of which he shows the large share taken in the production of aviation cameras by the Thornton Pickard Manufacturing Company. (P. 293.)

M. J. P. Clerc, of the French Aerial Photographic Service, has investigated mathematically certain important problems connected with the use of photography in the air, such as the estimation of the height of objects by the measurement of their cast shadows and the limit of angling which is permissible in taking photographs of a terrestrial region from an elevated standpoint. (P. 295.)

The aircraft camera, which proved to be one of the most efficient instruments used in the war, namely, that patented by Major F. C. V. Laws, is described in detail from the particulars given in the latter's patent specification. (P. 299.)

In a leading article, the first of a short series on the subject, we deal with the general attractiveness of stereoscopic photography, and endeavour to lay emphasis upon the things which appear to be chiefly responsible for its neglect by the great majority of amateur workers. (P. 290.)

The professional who makes a feature of copies of old originals can often attract a considerable bulk of business of this kind to his studio. (P. 289.)

Outdoor garden portraiture is a branch of work which should not escape the notice of those undertaking at-home portraiture. (P. 290.)

The publication in the autumn of an American annual of pictorial photographic work is announced. (P. 302.)

Metal spots on prints, registration of business names, titles on negatives, choice of studio lenses, and enlargement of large negatives are among the subjects briefly dealt with in "Answers to Correspondents." (P. 303.)

EX CATHEDRA.

Colonial, Last Hour.

As announced in this column a week ago, the last day fixed by our publishers for receipt of advertisements to appear in the Colonial and Foreign Number of the "British Journal" of June 6 was yesterday, when the arrangement of the very great number of advertisement pages was carried out in its all but final form. As those who have had any newspaper experience are aware, there is always a small margin in the "make-up" of advertisement sheets, which consist of announcements of many different sizes, and therefore we may perhaps say on behalf of our publishers that, while no guarantee can be given that further advertisements can be inserted, any orders, accompanied by "copy," which reach them by the first post tomorrow, Saturday morning, will be accepted, subject to its proving possible to find a place for them in the final adjustment of advertisement spaces. This intimation is made in order that any firms who may have overlooked the opportunity which is offered in this widely distributed issue should not thereby be unrepresented among the very great number of concerns in the British photographic trade who have been eager to renew their offers to buyers abroad.

Special Displays.

While passing through a provincial town recently we noticed a very interesting exhibit in a photographer's window. It consisted of a number of faded photographs of various descriptions, some copied the same size, while others were enlarged. The work was excellently done, and must have suggested to many passers by that something could be made of similar pictures in their own possession. We fear that most professionals are apt to shirk this class of work, considering it not worth the trouble involved, but unless a man has a very good business indeed he cannot afford to throw away any chance of making an extra penny. We can understand why copies were unpopular when shiny surfaces were the rule, but now nearly all prints are made upon matt papers it is much easier to get satisfactory results, as not only is the grain of the original less apparent, but the working up is much easier. It is surprising what a good effect can be produced with lead pencil alone, working in much the same way as in retouching a negative. An error which is often committed is to use a soft pencil with a blunt point, when, of course, the lines will show. A No. 3 retouching lead with a medium point is more suitable. The work can be fixed and the gloss, if any, removed by steaming, after which any necessary brush work can be added. Unless the operator is a very skilful artist he will do well to avoid anything in the nature of drawing upon the print, or the finished picture will have a cheap look. Some very fine results can be obtained by carefully spotting and then putting a thin

tint of black oil colour over the whole surface, wiping out high lights where required. This can easily be done with a little practice if a suitable medium be used.

* * *

Garden Portraiture. Many photographers who occasionally undertake home portraiture are apt in the case of feminine sitters to overlook the garden as a setting for fine and pleasing studies. We were recently looking at several garden portraits taken by a professional friend of a lady client among the flowers in her own garden that gave great satisfaction to all concerned, and for technical excellence and artistic merit left nothing to be desired. One word may be added on the technical side of such work. The photographer should take care that his pictures are of correct colour-rendering. It is certain that the lady sitter who desires to be photographed in her garden is a garden lover, and will probably resent her favourite yellow W. A. Richardson being rendered in the print as of ebony black hue. Therefore, it is important that panchromatic plates with a light screen, say, a K2, be employed for such work. With regard to posing and selection of the background, we need only add that the artistic perceptions of the operator are called forth in fullest measure, and shown to the highest advantage.

STEREOSCOPIC PHOTOGRAPHY.

I.—INTRODUCTORY.

THE time is well within the memory of many of us when the stereoscope was to be seen in every drawing-room: now it is rarely met with at all, and it seems to be regarded as an obsolete toy which had a charm in bygone times, but

a certain amount of prejudice against the stereoscope has been created by the deterioration of the stereograms. There are certain optical principles which require the closest attention if the instrument is readily to give the effects it is designed to produce. Indifference to these means that those effects are only imperfectly seen, and even then at the expense of a good deal of eye strain and discomfort, results which naturally enough tend to destroy that enthusiasm with which the wonders of the stereoscope were hailed when the invention was a new one, and when the slides were prepared with a more rigid regard for the exact essentials of perfect effect.

It is certainly a little disheartening to observe how much carelessness has crept into the production of commercial stereograms and how frequently the most elementary knowledge of the principles involved seems to be wanting. One frequently sees slides in which the pictures to be combined are separated by a full three inches or more. To anyone constantly accustomed to using the stereoscope this may present no serious obstacle to a due combining of the two; but to anyone looking for the first time it would almost certainly involve strain and patient effort before the blending could be effected. Worse technical defects than this are apt to occur. Not infrequently photographic prints are even mounted reversed so as to produce pseudoscopic instead of stereoscopic effects. One actually hears sometimes even a skilled photographer disputing as to whether it really makes any difference which of the pictures is mounted on the right and which on the left, while, so far as the science of stereography lapsed into oblivion, that many a modern photographer, professional as well as amateur, is quite unable to explain why the prints from a

A striking subject in the Stereoscope.

has long lost its attractive spell. There are several reasons for this change of fashion. In the first place, the instrument is inevitably associated with the Early Victorian period, and the present generation has very little sympathy with the fashions of that day. Secondly, the graceful box-shaped stereoscope has long been superseded by the much more serviceable Holmes form of the instrument, and unfortunately this contrivance, though so admirably adapted for its purpose, would be a most ungainly accessory in a modern drawing-room. Then, too, it is to be feared that

stereo negative require reversing before being mounted. As a matter of fact, the writer, when speaking to a professional photographer on this point recently, was shocked to find that he was not only ignorant that any transposition was needed, but had actually mounted considerable numbers for a customer without ever transposing and without any consequent defect having been observed by his customer in the results!

If, however, from these or any other causes stereoscopic photography has gone out of favour or fashion, there is

no question that a revival of interest in it is worth securing, and to that end all that is really indispensable is a little care and attention in regard to technical details and some comprehension of the general optical principles involved. Given only that the work is properly executed, no amount of familiarity with the results can entirely deprive them of the charm and fascination which they possess to those who see them for the first time.

Moreover, in these times of research there are many new applications for stereography that are of interest and value, and the stereoscope may be made a revealer almost comparable with a microscope or telescope. In astronomy and in radiography there are immense practical advantages in stereoscopic photographs, and there are other branches of science in which the value of stereograms is not less remarkable. To the artist, too, the presentation of natural objects in their true planes is a most instructive phenomenon, and the practical value of it to him would perhaps surprise him, if he would be at the pains to acquire the very easy knack of seeing stereoscopically without an instrument, as he would then find in the stereogram a model to all intents and purposes three dimensional, and one from which he could actually copy as from nature itself.

To achieve the requisite technical exactitude to render stereography once more popular and pleasing all that is really required beyond the usual essential of common-sense is a thorough realisation of the principle on which the phenomena of the stereogram depend. Briefly expressed, this principle is simply as follows: Our impres-

sions of solidity and planes of distance are derived from the mental effect produced by the two simultaneous retinal pictures of our eyes. The psychological reasons for this need not be theorised further than to say that long and uniform experience teaches us by association of ideas to infer solidity as the signification of these simultaneous dual retinal images. This being so, it is obvious if we can provide exact pictures of such dual images, and place them so that they present to the two eyes views exactly corresponding to two direct retinal images of the same scene, that inference of solidity cannot but take place. It matters not whether the two images are hand drawings, traced perspectively from the point of view of two eyes, or whether they are photographs taken with the twin lenses of a stereoscopic camera. The instinctive illusion of solidity must necessarily be caused in either case. As a matter of fact, it is interesting to remember that Wheatstone's original stereoscope, though invented in the time of Daguerreotypes, was not at first used to combine photographs, but only geometrical drawings of solids.

The object of the present series of articles is to give a few simple hints on the general principles of this rather neglected branch of photography, and if in doing so old ground has to be retrodren, those who are familiar with it will perhaps exercise forbearance, realising that to many others the subject is one that has been hitherto somewhat overlooked, to their considerable disadvantage as photographers and artists.

C. E. B.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

- A Talk About Lighting (Jan. 3).
- The Camera and the Lens (Jan. 10).
- Managing the Sitter (Jan. 17).
- Backgrounds (Jan. 24).
- Studio Exposures (Jan. 31).
- Artificial Lighting (Feb. 7).
- Printing Processes for Portraiture (Feb. 14).
- Studio Accessories and Furniture (Feb. 21).
- The Surroundings of the Studio (Feb. 28).
- Studio Heating and Ventilation (March 7).
- The Postcard Studio (March 14).

- The Printing-Room (March 21).
- About the Reception Room (March 28).
- Home Portraiture (April 4).
- Portable Studios (April 11).
- Copying (April 18).
- Handling the Studio Camera (April 25).
- More About Lenses (May 2).
- Enlargements (May 9).
- Advertising the Studio (May 16).
- Mounts and Mounting (May 23).

BUSINESS METHODS.

No photographic business is too small for some sort of book-keeping to be unnecessary. It need not be elaborate—in fact, the simpler the style adopted by anyone not skilled in office work, the more likely it is to be carried through. I am aware that it is possible to carry on business, and even to make a fortune, without keeping a note of any transaction; in fact, I can quote one instance of a man who could neither read nor write, and who had to Pelmanise the value of bank-notes and cheques by the number of times he folded them; yet he could afford a pint of Heidsieck with his lunch daily, and that without impoverishing himself; but he was in the greengrocery trade, which I think must be somewhat more lucrative than photography.

You may keep your accounts either in books, or, if you are progressive, upon cards; but in either case the method is the same, the bare essentials being a day-book, a cash-book, and a ledger. In the day-book should be entered at the time of delivery all goods sold—that is to say, that when a dozen

cabinets are sent home we should make an entry something like this:—

June 3. Mrs R. W. Tomson, 87, Belvedere Gardens.
1 doz. Cabinets, Bromide, £22s.

If the price has been paid in advance, this entry should have a distinguishing mark, so that a separate account need not be opened, the item being posted into the ledger under the heading of "Cash Sales." If only a deposit has been paid, or the whole amount is owing, a personal account must be opened in the ledger. In either case the cash when received must be posted opposite the entry. In the case of a cash sale the cash will naturally have to be posted first, and the entry will appear thus until the goods are delivered, when the amount charged will be filled in; until then the ledger entry will appear thus:—

A	B	C	D
Mrs. R. W. Tomson	£ s. d.	May 16 By Cash.....	£ 22 s. d.
			2 2 0

Columns A and C give dates of delivery and payment. B and D are for the page—or, as it is usually called, folio number—of the day-book and cash-book respectively. By this means we have an effective check upon errors, as if there is any discrepancy between the two amounts it can at once be inquired into. If Mrs. Tomson is a customer to whom credit is given, the account would appear thus when paid:—

Mrs. R. W. TOMSON, 87, Belvedere Gardens.

A	B	£	s.	d.	C	D	£	s.	d.
June 3 To Cabinets..	14	2	2	0	June 15 By Cash.....	9	2	2	0

If, however, at the end of the month the cash has not arrived, it is at once apparent and a statement of account is forwarded; when this is done, the actual date of doing so should be noted in pencil under the amount, thus indicating that it has not been overlooked.

The cash book is as important in its way as the ledger. On the left-hand page is entered all the money which is received and on the right-hand one all that is paid; thus:—

		B	£	s.	d.			C	£	s.	d.
June 5 Tomson, Mrs.		2	2	0	June 1 Greenfield & Co.		14	17	6		
Jones, A. J.		1	15	0	Wages		9	15	0		
Green, Miss					Gas		4	16	7		
A.		3	13	6							

Columns B and C are for the ledger folios on which the amounts are posted.

It will be noticed that there is no connection between the two sides of the cash book, and that it affords no indication of the progress of the business; for this we must go to the ledger which not only shows what has been paid or received, but what is owing to and by the business. I have mentioned only one ledger and this is sufficient for a small business. In larger concerns there are always two, one called the "sales" ledger for customers accounts, and the other called the "bought" ledger for goods purchased and money paid for the conduct of the concern, such as stockdealers, repairs, wages, gas, rates and taxes and other expenses. In all cases where the account is with a firm supplying goods or doing work it is what is called a personal account, but it is a good plan in addition to keep impersonal accounts as well, that is to say, that not only should we enter to the credit of the Empire Plate and Paper Co. an item of £25 17s. 6d., but also to the debit of another account headed Plates £15 17s. 6d., and to one headed Paper £10. Such accounts are memoranda only, but serve to show exactly how much has been expended upon these particular lines during the year or other such period as may be decided upon. In many large businesses this idea is carried out very elaborately, a special book being devoted to it. One firm with which I am acquainted can in this way ascertain day by day the expenditure on plates, papers, chemicals, packing, repairs, apparatus and many other items and any rise or fall in cost as compared with the quantity of work produced has to be accounted for. This is unnecessary for the small trader who carries much of this information in his head, but directly personal supervision of every detail in the business becomes impossible it is of the greatest value.

As far as getting invoices posted into the bought ledger or into that section of a single ledger for both bought and sold accounts there are two methods in general use, one being to enter them into a kind of daybook called the "bought journal" for which they are posted in the same way as daybook entries, and the other is to paste the actual invoices into a book and to post direct from this putting the ledger folio on the invoice. The latter method is the easier, but it is somewhat clumsy; moreover it does not permit of the total purchases being readily added up. I am sorry to say that many photographers I know are very lax in checking their accounts, some even taking the statement as correct and not troubling to compare it with the

invoices, entering it *en bloc* in the ledger to save trouble. The most honest firms make mistakes, the commonest one being to make a duplicate charge for the same article. This is easily detected if the invoices are carefully checked when they come in and initialled if correct.

The object of book-keeping is not only to avoid loss and prevent mistakes, but to give the trader accurate information as to how he stands financially, and in the case of disaster such as bankruptcy, the omission to keep proper accounts is regarded by the courts as a serious matter. If a question of compensation arises, as in cases of compulsory acquirement of premises for public improvements or by a railway company a proper set of books forms a firm basis for a claim, while in many cases the income-tax surveyor insists upon a proper balance sheet being submitted before he will pass a return of profits for assessment. It must not be forgotten that nearly everything connected with a business undergoes deterioration year by year, lenses and camera backgrounds and furniture do not remain long at their original value, and the trader is entitled to write off a certain percentage of this before he arrives at the amount of his net profits for the year. An omission to do this gave serious trouble in one case. On closing down a branch the greater part of the plant was sold at auction, realising only £25, the original cost being £300. On £275 being put down in the balance sheet as deterioration, the surveyor suspected fraud and made a searching investigation before he allowed the claim. If this had been spread over, say, ten years, it would not have excited comment.

I would strongly advise anyone having a photographic business with a turnover of more than £1,000 a year to have his books audited and a proper balance-sheet prepared by a professional accountant annually, as this is not only useful, for the reasons already given, but also furnishes very useful information to the proprietor himself. The bank balance is not an unfailing guide to one's circumstances. Outstanding liabilities and assets have also to be considered, and these may put quite a different complexion upon things. When a business has branches connected with it, very careful supervision over expenditure is necessary. For example, it should be clearly ascertained whether the quantity of material used bears the same proportion to the quantity of work turned out as in the head establishment, which is presumably under the eye of the proprietor himself. It is not unknown for a manager to execute orders on his own account, using his employer's material, and in other cases to waste plates and paper by careless working; in one recent instance a reduction of nearly £20 a month in cost of material was made by a change of management, the gross takings being actually increased. This would have been discovered at an early stage if proper accounts had been kept.

The collection of outstanding accounts is a matter requiring some tact, the main object being to use just as much pressure as is possible without offending the customer. I do not say never resort to county court proceedings, but do so as rarely as possible. I have known photographers and others with slipshod methods who have taken out a long list of old debts and sent it to their solicitors or a debt-collecting agency for proceedings to be taken. Such an action shows slackness in everyday routine. If proper discretion be exercised in granting credit, and accounts regularly rendered, few doubtful debts will be made. I have found one or two little dodges useful in bringing slow payers up to the mark. One is to add a charge for postage of previous applications to the original amount; that is to say, if the bill has been sent in six times, on the seventh application is added in red ink: "Postage of previous applications, 9d." This generally brings the money, but usually minus the postages. Another useful ruse is to make a considerable error (?) in the amount; that is to say, for a debt of £3 10s. to ask for £5 10s. This usually brings

a rather sharp letter of correction enclosing a cheque. As a last resource before threatening action, I have sent a letter asking if any error in the account stood in the way of payment, or if a remittance had been sent and lost. With this was enclosed a stamped addressed envelope for reply, and this three times out of four came back with the desired remittance. These little hints will, I hope, not be so much needed by the portrait photographer, who can usually get payment at the time of sitting, as by the outdoor and commercial man who generally has to trust his clients.

I may add that it is generally advisable, if court proceedings are contemplated, to put the matter into the hands of a solicitor or debt-collecting agency. Very often the solicitor's letter of application will suffice, and in the event of the case going into court all expenses have to be paid by the defendant. One vital point in such cases is proof of delivery of the goods; one cannot sue for goods made and not delivered. If for any reason a customer chooses to refuse acceptance, say, of an enlargement after it has been tendered at his address, there would probably be ground for an action providing that the order can be proved to have been given; but as a rule

it is possible actually to deliver the goods and let the customer return them if he chooses.

When either buying or selling, unless the transaction can be completed on the spot, it is desirable to ask for or to give an estimate of cost. This will often obviate unpleasantness. If alterations or repairs to premises or apparatus are needed, it is satisfactory to know just what you ought to get for your money, while in the case of doing work such as the production of any special picture which is not on your price list, it is equally useful to have the price fixed. I have suffered from this by such shabby tricks as having the customer say: "You have charged me three guineas and a half, and you told me it would cost two guineas and a half, and I certainly will not pay a penny more." What is to be done? It is either keeping the picture at a dead loss or losing the guinea; for even if one were disposed to take it into court, it is only one party's word against the other.

I have not in this talk touched upon such subjects as card indexes, registration of orders, and work sheets, as these will require a separate article to deal with them adequately.

PRACTICUS.

CAMERAS FOR AVIATION PHOTOGRAPHY.

[We are gradually getting the whole story of the development during the war of aerial photography. The design and production of lenses have had their chroniclers in the representatives of the firms concerned. And now the Thornton-Pickard Company, who were the very first and, as we understand, the very largest producers of cameras for military aerial work, are fortunate in having as their historian Mr. Spencer Leigh Hughes, M.P., by whom, for once in a serious vein, the article which we reprint below has been written, and is issued as an introduction to the catalogue of Thornton-Pickard manufactures just issued. The tale is not yet complete, for we have in type a contribution by Mr. Colin M. Williamson which will show the share taken by this inventor and designer in providing apparatus for the detection of the enemy's works and movements. And even then we shall not have dealt with contributions, by no means inconsiderable, of the Allies. M. L. P. Clorc, to whom the working out of a number of scientific problems involved in aerial photography is due, has kindly sent us copies of his papers, translations of which we are publishing in due course. EDS. "B. J."]

THE phrase "aviation photography" would have puzzled nearly everyone a very few years ago. To us to-day it includes the notion of flying, of taking photographs from a machine moving quickly at about a mile and a-half above the earth, and doing this in war time, picking out and revealing all sorts of unsuspected details in the enemy's area with decisive and, so far as the enemy was concerned, deadly results. All this is accepted as a matter of course to-day, but in this form of enterprise, as in all others, such as iron-clad vessels on the sea and railways on the land, the pioneers had a hard task at the start.

So far as aviation photography is concerned, two of the pioneers were Lieut. G. D. M. Campbell (who is, unhappily, no longer living) and Lieut. J. T. C. Moore-Brabazon, now a Lieut.-Colonel and Member of Parliament for Chatham. I have heard him tell the House of Commons how he and some other hopeful enthusiasts went to the War Office in 1911, barely three years before the war, offering to provide a couple of aeroplanes if the authorities would allow them to be used experimentally at the Army manoeuvres of that year. The officials declared that aeroplanes were not wanted for war purposes, and that no one could see any use for them, and even in 1915, after months of war, when photography was offered as an aid for reconnaissance purposes, the authorities, while being good enough to say that the photographs taken were "pretty things," once more declared that no one could see any use for them from a military point of view.

In fairness to the War Office, I ought to say, in passing, that the Admiralty was just as disinclined to have anything to do with these new proposals. It is well for us that our pioneers are not easily discouraged, or, if discouraged, not stopped in their determination to keep pegging away, and the struggle against scepticism, indifference, and prejudice was continued.

There was a young officer, who is now a famous general, who used to go about with his pocket full of photographs, handing them out as if they were commercial travellers' samples, with the pathetically

modest suggestion that perhaps they might be found useful. And so the game continued until one day in February, 1915, certain photographs of the enemy's position were taken with a miserable makeshift camera, but the result made the authorities sit up and take notice.

All sorts of unsuspected things were revealed, such as unknown trenches, while sham trenches were shown to be shams. The staff got busy, the general vowed he could capture the enemy's position next day, and he did so with complete success, taking many prisoners without one casualty on our side. After that, aviation photography was recognised as an art that can produce results other than mere "pretty things."

One of the first difficulties to be tackled was the flat, hazy, and vague appearance of pictures taken from a mile and a-half up, say, in Flanders. What these pioneers wanted to do was not only to eliminate lack of contrast, but, if possible, to emphasise contrast, and this they soon did. For instance, they turned their cameras over dark, ploughed fields or great brown stretches of mud, across which ran paths mud-coloured like their surroundings, and in the photographs these paths stood out as white lines. Again, German guns, so cunningly disguised as to be quite invisible by the keenest eyed observer, were picked out and revealed by the camera. By this time it was obvious that a new method of war of enormous value had been discovered, and now it is only fair to say that General Headquarters began to get busy in a manner worthy of the best British traditions.

The two young officers, Lieutenants Campbell and Moore-Brabazon, were sent hurriedly over to England with instructions to get cameras suitable for the purpose. Directly they reached London they telephoned to the Thornton-Pickard Manufacturing Company, Ltd., of Altrincham, asking for a representative of the firm to be sent to London in order to discuss the designing and-making of a camera for aviation photography. Once more there was no delay. Mr. R. Hesketh, the secretary of the company, reached London the same night—a Friday—and on Saturday morning he and the two officers were hard at work discussing the problem. Mr. Hesketh hurried

back to Altrincham, work was at once begun, and within three days the first British aviation camera for war purposes was designed for the Royal Flying Corps, and was ready for examination by Wednesday, or, as I have said, in the record time of three days.

Moreover, they had to carry out quite special suggestions which the experience of the officers enabled them to give. For instance, it had been found that the vibration in a flying machine is so enormous that it tends to loosen all ordinary screws. The makers, therefore, substituted metal thread screws, secured with screw-nuts, instead of the usual wood screws. As I have said, the camera was ready for examination by the Wednesday, one or two minor alterations were made, it was delivered to the War Office, and was hurried over to France on the Saturday—a fine bit of work, reflecting credit on both the military and manufacturing authorities. Moreover, when once the War Office had recognised the usefulness of this development, they extended it enormously.

At the start it employed but the two lieutenants and a sergeant, now Major Laws, who to-day holds a high position at the Air Board. Before long there were many thousands of men connected with the photographic section of the Royal Air Force. The first cameras sent out were effective and useful, but in all inventions and discoveries there is room for improvement, and the enthusiasts who had started this memorable movement were not men who would be satisfied with anything that was second best.

In a very short time one type of camera superseded another, each being a marked improvement on its predecessor. In the summer of 1915, Mr. Gray Pickard, the manufacturing company's general manager, was requested by the War Office to go out to the General Headquarters of the Flying Corps in France to discuss the subject of aviation cameras still further. The result of these consultations was soon seen in further improvements, and highly effective cameras were made in very large numbers. They were in use not only on all the war fronts, but also employed for training purposes in all home, Colonial, and Allies' camps. Though, as I have shown, there were some of the authorities at the outset who were blind to the advantages of this new discovery so far as war purposes were concerned, those advantages were so obvious directly the invention was given a fair chance that aviation cameras were in demand everywhere, right up to the end of the hostilities.

It used to be said that Wellington owed much of his success as a soldier to the fact that he could by intuition or genius make out what was going on at the other side of a hill. And ever since war has been known in the world, commanders have always been anxious to find out what the other fellows were doing.

The Germans certainly made great efforts to deceive our side by all sorts of methods and devices, but they were foiled to a great extent by these mechanical detectives, as they may be called. It was in vain that they moved their trenches, as they did continually, and in vain, too, that they tried by all sorts of means to disguise or hide their guns, for the aviation cameras revealed and recorded all their moves and tricks. They were in a real sense of the word the eyes of the Army. Nor should it be supposed that they were useful only in revealing the secrets of the enemy, for photography has been of enormous assistance in the recent war to our artillery. It is a fact that every gunner thinks he knows exactly where his shot goes, the fact being that he does not. Such a remark from a layman and civilian like myself would be presumptuous if made only on my own authority.

The statement has been made by Col. Moore-Brabazon, and confirmed by many soldiers; indeed, the Colonel has put the matter on record in this way: "It was not until we actually showed the marks made by the shells, by photographs, that they were practically forced to use aeroplanes for firing heavy guns. On that matter I remember well an officer flying over Ypres salient and sending back by wireless a curious message, 'that if anyone was firing at the centre of the lake'—the name of which he gave—he was hitting it." No one will to-day deny that aeroplanes have played a great part in directing artillery fire, but from the above quotation it seems that it was photography from above that really convinced the gunners that they were wrong in supposing they knew where their shots were going. So that here once more the aviation camera helped our cause most decidedly.

Nor have I even now mentioned all the advantages resulting from the use of this ingenious invention, as all sorts of useful knowledge

has been obtained in this way. Long before the end of the war it became one of the chief features of war in the air and down on the land, too. For as it was possible to know accurately the height at which photographs were taken, and the focal length of the lens used, the photographs could be made into scale plans, and it was from these plans that our attacks on the German defensive system were made. And in this way a method of producing what were dismissed as merely "pretty things" came to play a decisive part in the grim realities of war.

And now let me tell the reader of another development of aviation photography, so ingenious that it might well appear incredible had it not been used in practice, and used with remarkably successful results. To begin with, I may explain that while a man may be a very good machine gunner on the ground, he may be a very poor shot with a Lewis gun in an aeroplane, hardly ever making a hit. That is to say, he would be of no use so far as injuring the enemy is concerned, and at the same time he would inevitably be himself shot down sooner or later. But it was virtually impossible with an ordinary machine gun to prove whether a man was or was not a good shot from a flying aeroplane. It was then suggested that a camera just like a Lewis gun should be made in order to train flying machine gunners, or to find out those who could not be trained and to weed them out in the interests both of themselves and the service.

I have seen and examined one of these machine gun cameras, known technically as the Mark III. Hyde gun camera, and I may say that even experienced machine gun officers have supposed, until they have examined the invention, that it was an ordinary Lewis gun. The fact is, that in appearance and in operation it and a Lewis gun are identical, but instead of firing a bullet the gun camera takes a photograph. There are many advantages in this. To begin with, as the process of firing a Lewis gun is exactly the same as of photographing with the gun camera, the man who is taking the photographs is at the same time learning how to use a Lewis gun. But there are more important advantages than that, for the gun camera shows and records on the film how many hits the man would have made had he been firing bullets at the aeroplane which he is photographing.

There are ingenious little devices, somewhat of the nature of tell-tale clocks, that make it impossible for a man successfully to tell a too flattering tale about his performances in the air, especially in regard to how many drums of ammunition he has used. Not the least useful purpose served by working the gun camera is the fact that it teaches men how to judge and estimate correctly distances in the air. It is very difficult for a man to feel sure as to how far off an enemy aeroplane is, and yet it is of vital importance that he should learn to do so. Machine guns on aeroplanes are sighted for point-blank firing, and obviously if bullets are fired point-blank at an enemy who is just out of range the bullet misses because it begins to drop, however accurate the aim of the aerial gunner may have been.

In connection with this I may mention a favourite device of the enemy in the earlier days of aerial warfare. I am one of those who think that in many respects we gave the Hun undeserved credit for astuteness and especially for accuracy as a student of psychology and mentality. For instance he blundered miserably in his view that our great Dependencies and Dominions would say that the war was a European affair and would refuse to help. Also he was wrong in supposing that India would rebel. It was actually believed by Germans of high positions that suffragette troubles in this country would paralyse us by keeping our army at home. But in one of his calculations the Hun was right. He knew he could rely on our young airmen being "sports" and ready to take risks, and the Hun traded on that knowledge with some success. For he would keep just outside point-blank range until the British aviator had emptied his magazine, and then, before there had been time to change the drum, the German would dash in and bring down his enemy. Things happen very quickly in the air, and a few seconds makes all the difference. Many a man on our side lost his life in this way, and it became imperative that some means should be discovered of teaching this important lesson of how to judge distances in the air. The gun camera does this, and soon after the authorities had given what was at first a reluctant consent to have it used for training purposes a very great improvement in the shooting of

British aviators was noticed. Indeed, it was so remarkable that it could not be dismissed as a mere coincidence.

Before long this Mark III. Hythe camera was recognised not only by our Air Force, but by the air forces of all our Allies as essential for training flying men, and large numbers were supplied to France, Italy, America, and other Allies, as well as to our own aviators. The demand for these machines was so great, and went on increasing right up to the day the Armistice was signed, that the Thornton-Pickard Manufacturing Company had to give up making their ordinary types of cameras and concentrate entirely on this sort of work for the Air Ministry. Those who are capable of forming a definite opinion that is worth anything on this matter, declare that this Mark III. gun camera was the main factor in the supremacy of our men in the air, and for their absolute dominance over the enemy. In the realm of war, as elsewhere, the proof of the pudding is in the eating, and those who suggested the use of the gun camera as a means of improving our airmen's shooting could and did point out that as soon as the experiment was tried the hoped-for results were obtained.

I regard the history of how the arts of flying and of photography were developed and united in the war, and how they came to be chief factors in the war being won, as really a fascinating tale that has the merit of being true. And I also think it is a record that does credit to our race. It is certainly a mistake to despise your enemy, but it is also a mistake to over-estimate his gifts and to depreciate those of your own side. We have beaten the Germans in nearly every invention or development of engines of war. Even in regard to poison gas, which we had no intention and no wish to use, and the use of which was forced on us, ours was more deadly than theirs. But it is in the realm of aviation photography that our supremacy has been most conspicuous.

Indeed we have excelled not only the enemy, but have been able to give a lead to all our Allies in this respect. It is true, as I have shown, that at first naval and military authorities were hostile to both flying and photography as a means of war, but let us not make too much of that. I may confess that about twenty years ago I wrote an article to show that flying machines heavier than air that would rise to a great height and would remain up a considerable time and go far, would never be made, because they could not. And a much greater authority than I am, the late Lord Kelvin, who could write after his name G.C.V.O., M.A., LL.D., D.C.L., F.R.S., F.R.S.E., and D.L., and was a Professor of Natural Philosophy, with honours from nearly every university in the world, said just what I said, that the things were impossible. Fortunately for mankind our inventors, discoverers, and pioneers are men who, in the language of the old hymn, "laughs at impossibilities and cries it

shall be done." Thus we may forget the original hostility of a few in connection with aviation photography and recognise rather their promptitude in scrapping their old notions, and their eagerness to help forward new inventions which had been proved to be practicable. From that point the history of effort, experiment, improvement, and in the end of triumphant achievement, is pleasant reading.

The persistence of the young officers, the energy and skill of an English manufacturing firm, masters and men alike, are refreshing incidents in the record, and it is well to dwell on them, because, as I have said, there are too many people prepared to enlarge gloomily on our supposed decadence as a race, or at least they were inclined to do so before the war. Few of us in this country had any notion as to what was going on in that memorable week between the Saturday, when Lieuts. Campbell and Moore-Brabazon met and consulted with Mr. Hesketh, the secretary of the Thornton-Pickard Manufacturing Co., Ltd., of Altrincham, and the following Saturday, when the first British aviation camera was taken to France. Perhaps, if we had known we might not have appreciated the importance of the affair—but in those seven days something had been schemed, explained, made, altered, and sent to the Front, that as much as any other one thing made the overthrow of the enemy absolutely certain. When I first met Mr. Hesketh in a club in London he came in armed with a Mark III. Hythe gun camera, and when he took it from the case I thought it was a Lewis gun. Thus when he began clicking away, as if firing it, I was scared and felt tempted to get under the table. But when he opened what seemed to be a deadly weapon and explained and exhibited its mechanism, my alarm was changed into admiration approaching fascination. For here was an invention that I really believe gets as near to perfection as any human invention can. It contains more than 200 separate parts, and yet anyone can carry one with ease.

I have already shown how supremely important aviation photography has proved itself to be in the war, and it is pleasant to know that it may be, and as I feel certain it will be, equally useful for the purposes of peace. It can be employed for surveying and preparing plans and maps of remote districts, difficult to travel through, but easy to fly over. By its aid water-ways, sites for harbours or docks, and indeed all the contour of a country can be observed and recorded, and what is more will be recorded with absolute accuracy. Thus those who are responsible for aviation cameras may have the satisfaction of knowing that not only have they "something attempted, something done" for their country and its cause in war, but they have also produced instruments for adding to the knowledge, the prosperity, and therefore the happiness, of mankind in peace.

SPENCER LEIGH HUGHES, M.P.

CALCULATIONS IN AERIAL PHOTOGRAPHY.

[The following are short papers by M. L. P. Clerc, representing calculations worked out by him for the French Aerial Photographic Service in the course of his connection during the greater part of the war with that body. We owe to the kindness of M. Clerc the use of his French manuscripts and of the illustrative diagrams. Eds. "B.J."]

LOWERING OF THE HORIZON LINE IN PHOTOGRAPHS TAKEN FROM HIGH-VIEW POINTS.

In panoramic photographs taken from elevated positions, and particularly in photographs made from balloons and aeroplanes, the horizon line of the landscape does not coincide with the principal horizon line—that is, the intersection of the plane of the negative and the

Fig. 1.

horizontal plane containing the nodal point of emergence of the lens—but below this line there is an apparently lower position of the horizon, the depression being greater as the view-point is higher and the focal distance of the lens is greater.

In Fig. 1 let O be the centre of the earth, and S the supposed view-point at an altitude $SV = h$ above the mean surface of the earth. The apparent horizon is the intersection of the plane of the negative and the tangent plane ST, drawn to the sphere from the point S. The principal horizon plane is SH, drawn from S at right angles to the radius of the earth's circumference, SO. If we call n the angle included by these two planes, and if F be the focal length of the lens used, the depression, d , of the horizon line on the negative will be measured by

$$d = F \tan. n.$$

Produce the radius, SO, to the antipode, N, and express the power of the point, S, relatively to the meridional circle of radius, r :-

$$ST^2 = SV + SN = h(2r + h).$$

In the right-angled triangle S O T, the angle at O is equal to the angle, n . Therefore,

$$\tan. n = \frac{S T}{O T} = \sqrt{\frac{2h}{r} + \frac{h^2}{r^2}}$$

As a first approximation, quite sufficient in practice¹, the quantity h^2/r^2 can be neglected. The ratio $h : r$ is actually less than 1 : 1,000 for heights, h , of 6,000 metres. We can, therefore, write

$$d = F \sqrt{\frac{2h}{r}}$$

which gives the value of d when we know the focal length of the camera used; the altitude of the view-point and the mean radius of the earth = 6,371,004 metres.

For each value of F (the focal distance) a curve can be constructed giving the values of d as a function of the value of h , this curve being a parabola, for which the equation is

$$d^2 = \frac{2F^2}{r} h$$

But for the construction of a series of curves giving the value of d in all cases it is simpler to set off (fig. 2) the altitude, h , as abscissae, and the values of d^2 as ordinates—i.e., the squares of the values

(1) Apparent deviation of the horizon by atmospheric refraction is neglected.

(2) The graphical construction is facilitated by noting that for an altitude of 3,185 metres (1/20000 of the radius of the earth) the values of d^2 are approximately equal to the squares of the focal distance.

If the optical axis is not horizontal at the time of taking the photograph, but is at an angle ω below the horizontal plane, the expression of the corresponding depression d becomes rather complex.

$$d_{\omega} = \frac{F \sqrt{2} h}{\text{Sin.}^2 \omega \sqrt{2} h + \text{cos.}^2 \omega \sqrt{r}} \quad \frac{F (\text{tan.}^2 \omega + 1) \sqrt{2} h}{\text{tan.}^2 \omega \sqrt{2} h + \sqrt{r}}$$

ESTIMATION OF THE HEIGHT OF OBJECTS BY THE MEASUREMENT OF THEIR CAST SHADOWS IN AERIAL PHOTOGRAPHY.

THE height of a building, fortification or wall, or the depth of an excavation or trench, the difference of heights between the ridge of a mountain and the point to which its shadow extends can be determined in vertically taken photographs¹ of known scale by the dimensions of cast shadows.² The degree of approximation is closer according as the scale of the photographs is greater and the shadows long as when the photographs are taken as early or late in the day as the light permits.

If an object of known height occurs in the field of the photograph it is easy to compare the height of any other object which casts a shadow. Calling h the height of the known object, l the length of its shadow, h' the unknown height of an object casting a shadow of length l' , then

$$h' = l' \frac{h}{l}$$

But such a comparison method is often impossible. In the case of photographs of inaccessible regions it is necessary to have recourse to the determination of the length of the shadow of an object of known height at the same time of day on the day following or within a day or two of taking the negative. Variation from one day to the next in the length of the shadow at the same time of day is negligible.

It is, however, possible by calculation to dispense with this determination, which, moreover, is impossible when a photograph not of recent date is being examined. Tables of longitude and time indicate for all the days in the year the time of the passage of the sun to the meridian of Paris (true local noon) and the corresponding value of the declination (angle of the plane of the earth's equator with the straight line joining the centres of the earth and the sun). The variations of declination from one day to another are, moreover, so small that the sun may be considered as occupying a fixed position in the ecliptic from dawn to sunset.

On these data I have calculated a reckoner in the form of the chart (fig. 1)³ directly utilisable at the region of Paris. The point in the intersection of the horizontal corresponding with the date of

(1) It is customary to describe as "vertical" photographs those made from the air with the lens-axis vertical; the plate horizontal.

(2) The methods of estimation assume, in direct calculation, that a particular object casts its shadow on a horizontal plane (apart from corrections for inclination indicated above), or in the case of comparison observations, that the objects cast their shadows on parallel planes.

sought. The curves corresponding with each value of F are then straight lines².

In all operations requiring a knowledge of the principal horizon line (correction and reconstitution of perspective) allowance for this shift

Fig. 2.

should always be made, or, at any rate, when the camera fitted with an indicator of inclination does not show directly on the negative the position of the principal horizon line. L. P. CLERC.

the exposure and that of the vertical (approx.) with the time of the exposure is either on one of the curves or comes between two

The figures marked on the various curves indicate, in metres, the length of the shadow cast by a vertical rod of 1 metre height on a horizontal plane at all hours of the day (local French time), and for all periods of the year. In the use of the table the necessary allowance requires to be made for "summer time." To allow for differences of longitude, set back the time noted 4 minutes for each degree of longitude E. For greater accuracy the following coefficients can be used within the limits of latitude 47 to 51 degrees.

For values of co-efficients up to				
add per degree of latitude above 49	2	3	6%	6 1/2%
subtract per degree of latitude less than 49	5%	5%	5%	6%

Fig. 1.

curves. The number marked on a single curve or a number intermediate between those on two adjoining curves indicates in metres

the length of the shadow on a horizontal plane of an object one metre in height at the times of day and year in question. Thus, all that has to be done is to divide by this number the length of a cast shadow measured in the photograph in order to obtain, on the scale of the particular photograph, the height of the object casting the shadow.

The curve applies also to any other point of the same latitude (49° N.) by suitable modification of the scale of times (daily), adding four minutes to the time for each degree of longitude west of Paris (or subtracting four minutes for each degree east). It is not applicable to places situated to the north or south of the parallel of Paris, the error amounting to 15 per cent. for a variation of 2° of latitude (parallel of Belfort or Dunkirk) when the shadow is four times the height of the object. It is, therefore, necessary to construct a suitable chart for each region, having calculated the required co-efficient.

At any instant when the zenithal distance of the sun (angle of

Fig. 2.

the vertical of the place with the line from this place to the centre of the sun) is γ , the length A'B (fig. 2) of the shadow cast by the object AB in the horizontal plane of A' is

$$A'B = AB \tan \gamma.$$

In calculating the angle γ take three co-ordinates (fig. 3), one of which Oz coincides with the line P'P' of the poles, the plane xOy being the plane of the equator, and the plane xOz that including Ox and the centre S' of the sun at true noon, the direction OS' making with Ox the angle δ equal to the known declination. Consider then in the plane xOz a point M₀ of the latitude ϕ . For this point the sun is at the meridian (true noon). The zenithal distance γ_0 , the angle of the vertical M₀V, and the line M₀S₀ of the sun is equal to M₀OS', and therefore

$$\gamma_0 = \phi - \delta \dots \dots \dots (1)$$

(1) Reproductions of these charts were officially issued as blue prints to the French army officers in July, 1917.

(2) If the shadow, instead of being cast on a horizontal plane falls on an inclined plane, the angle which the shadow makes with the horizontal being called σ the length L of the shadow and its projection L' on a horizontal plane are:—

$$L = \frac{h \sin \gamma}{\cos(\gamma + \sigma)} \quad L' = \frac{h}{\cos \gamma + \tan \sigma}$$

σ is reckoned positively or negatively according as the extremity of the shadow is lower or higher than the foot of the object.

(3) During the period of the advance of the clock (Summer Time) the time is reckoned one hour less in order to compensate for the modification.

At every instant other than the true noon, the point of the earth in question has come into M such that the angle M₀Om of the corresponding meridian is equal to 15 t, t being the interval of time in hours between the true noon and the moment in question (the rotation of the earth is 360° per 24 hours = 15° per hour). The corresponding zenithal distance is the angle VMS = VOS'. From M let fall a perpendicular MM' on OS'. The co-ordinates of M.

Fig. 3.

and M' are respectively, taking the earth's radius as unit of length:—

$$\begin{matrix} M & & M' \\ \left\{ \begin{array}{l} x = O_1 M \cos. 15 t = \cos. \phi \cos. 15 t \\ y = O_1 M \sin. 15 t = \cos. \phi \sin. 15 t \\ z = O_1 O_1 = \sin. \phi \end{array} \right. & & \left\{ \begin{array}{l} x = O M' \cos. \delta = \cos. \gamma \cos. \delta \\ y = 0 \\ z = O M' \sin. \delta = \cos. \gamma \sin. \delta \end{array} \right. \end{matrix}$$

The value of the angle γ is obtained by remembering that MM' is perpendicular to SS' and that therefore the sum of the projections on OS' of the projections of MM' on the three axes of the co-ordinates is zero.

$$(\cos. \gamma \cos. \delta - \cos. \phi \cos. 15 t) \cos. \delta + (\cos. \gamma \sin. \delta - \sin. \phi) \sin. \delta = 0$$

or, after simplifying,

$$\cos. \gamma = \cos. \phi \cos. 15 t \cos. \delta + \sin. \phi \sin. \delta \quad [2]$$

For the determination, point after point, of each curve corresponding with a suitably chosen value of $\tan \gamma$, γ and ϕ being fixed, the method has been to calculate for periods of about 10 days, expressing t in functions of δ . The times t thus determined were then set out, starting from true noon, for the two dates of the year having the same value of δ . Each calculation thus yields four points. The intersection of each curve with the curve of true noon were supplied by the equation (1).

L. P. CLERC.

ON THE LIMIT OF ADMISSIBLE ANGLING IN VERTICAL OR HORIZONTAL PHOTOGRAPHY.

In fig. 1 consider a photograph made from the viewpoint S with a lens of focal length F the axis S. P. of which makes an angle w with the vertical S V and compare this image with that which would have been obtained from the same point with the same lens directed vertically downwards.

Let T and T' be the planes of the respective images, I J their intersection (axis of collineation of the two images), and P and P' their principal points. It will be noticed that along their intersection I J the two images are identical and that the distances I P, I P' of the principal points from this intersection are equal to each other, and to $F \tan \frac{w}{2}$.

In the plane, containing the vertical from the point S, and perpen-

dicular to I J, draw a horizontal meeting the plane T in H. This point H is thus the vanishing point of the images of the horizontals parallel to P' I. It can be easily (1) shown that

$$I H = H S \frac{F}{\sin. w}$$

A certain point of the region photographed forms its image in A in the plane T and in A' in the plane T'. The plane which contains S H and this point cuts the plane T along H A and the plane T' along A'. We will now determine in the plane T the co-ordinates of the point A relatively to the axes I J and I P as a function of the co-ordinates of the point A' in the plane T' relatively to the axes I J and I P'.

From A draw Aa parallel to I J. From the similar triangles H A a and H a I

$$\frac{Aa}{aI} = \frac{H a}{HI} \text{ or } \frac{x}{x'} = \frac{\frac{F}{\sin. w} + y}{\frac{F}{\sin. w}}$$

whence we have

$$\frac{x - x'}{x} = \frac{y}{\frac{F}{\sin. w} + y} \quad x - x' = \frac{xy}{\frac{F}{\sin. w} + y} \quad [1]$$

From the similar triangles H A S and a A A' on the one hand and H A a and H a I on the other, we have—

$$\frac{aA'}{HS} = \frac{Aa}{AH} \quad \frac{Aa}{AH} = \frac{Ia}{Ha}$$

whence

$$\frac{aA'}{HS} = \frac{Ia}{Ha} \text{ or } \frac{y'}{F} = \frac{y}{\frac{F}{\sin. w} + y}$$

whence

$$\frac{y - y'}{y} = \frac{y}{\frac{F}{\sin. w} + y} \quad y - y' = \frac{y^2}{\frac{F}{\sin. w} + y} \quad [2]$$

In order that a point of the image T shall coincide with the corresponding point in the image T', it is necessary that after bringing T

Fig. 1.

on to T' along the common axis I J, the distance of the two corresponding points should be less than the admissible error of definition ϵ , condition which may be written:—

$$(x - x')^2 + (y - y')^2 < \epsilon^2$$

or, substituting for these differences their values found in (1) and (2)

$$x^2 \frac{y^2}{(\frac{F}{\sin. w} + y)^2} + y^4 < \epsilon^2$$

The area of the oblique photograph susceptible of being united with the vertical photograph taken from the same view-point is therefore limited by the curve:—

$$x^2 = \frac{\epsilon^2 (\frac{F}{\sin. w} + y)^2 - y^4}{y^2}$$

the form of which recalls that of a *Nicomedes conchoid* of which the axis IJ is the directrix.

By way of example, a series of these limited curves has been traced (fig. 2.) on centimetre squared paper for different values of

¹ It is seen that I H = I P + P H. But I P = F tan $\frac{w}{2}$, and P H = F cot. w. By addition and expression of cot. w as a function of the trigonometrical lines of the angle $w = \frac{w}{2}$ we have—

$$I H = F \left(\tan. w + \frac{1 - \tan. w}{2 \tan. w} \right) = \frac{F}{2 \sin. w \cos. w} = \frac{F}{\sin. w}$$

and—

$$S H = \frac{F}{\cos. w} \quad \frac{F}{\sin. w}$$

the angle w which in the case of photographs made with a 26cm. lens, allowing an error of definition of 0.02cm. (1/5mm.). These curves are brought into correspondence with the horizontal line of each negative drawn by the principal point. Plainly the same considerations would apply to panoramic photographs made with the optical axis of the lens inclined at an angle below the horizon. But most usually the panoramic photograph is employed only with the measurement of horizontal angles, all the important points of the image being first

Fig. 2.

projected on a horizontal line of the plate. In this case the variations of the ordinates are no longer of effect on the exactness of the measurements and it is sufficient to limit the regions of the plate to the interspace of which the differences $(x-x')$ are less than the admissible error of definition. The limiting curves will be defined by the condition

$$x - x' = \pm \epsilon$$

or, substituting for this difference its value previously calculated (1),

$$xy = \pm \epsilon \left(\frac{F}{\sin. w} + y \right)$$

an equation which (after removal from the axis of the y's of amplitude equal to ϵ and therefore negligible) becomes:—

$$xy = \pm \frac{\epsilon F}{\sin. w}$$

that is, corresponding with two equilateral conjugate hyperbolas the asymptotes of which are the common axis IJ, and a perpendicular to this axis from the principal point.

Fig. 3.

Fig. 3 is a series of such limiting hyperbolas traced for different values of the angle w in the case of photographs made with a 26 cm. lens, and with an error of definition of 1.5 mm. These curves have been brought in each case to the horizontal line containing the principal point. At the same time, except for the horizontal

error of 0°-30' the position corresponding with the intersection of the plane of the image and the horizontal plane containing the viewpoint S has been shown.

It will be seen that in the case of a vertical or horizontal error of half a degree the useful surface (12 x 17) of a 13 by 18 plate is comprised wholly within the limiting curves which correspond with an error of definition of 0.02 cm. (2 metres at 2,600 metres). The angle indicator suitable for such a camera for photogrammetric purposes should therefore read to within nearly half a degree in order to obtain a plan of the required accuracy.

L. P. CLERC.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, May 5 to 17:—

PRINT DRYER.—No. 11,651. Means for drying photographic prints. S. H. Morse.

CINEMATOGRAPHY.—No. 11,395. Cinematograph apparatus. O. D. Binger and J. Stoop.

PROJECTION APPARATUS.—No. 11,549. Apparatus for projecting images upon a screen. R. G. Cave and R. O. Harmes.

CINEMATOGRAPHY.—No. 11,431. Shutters for cinematograph cameras and projectors. F. van Neck.

CINEMATOGRAPHY.—No. 11,430. Focussing devices for cinematograph cameras.

PROJECTION SCREENS.—No. 11,576. Screens for cinematographs, lanterns, etc. H. Proud.

CINEMATOGRAPHY.—No. 11,791. Screen for cinematograph projection. A. Villers.

TRIPODS.—No. 12,439. Photographic tripod stands. M. Belasnie.

VIEW FINDERS.—No. 12,469. View finders for cameras, etc. L. B. Jones.

LENS HOLDERS.—No. 11,861. Means for securing lenses, etc., in holders. A. B. Forster.

PROJECTION SCREENS.—No. 12,030. Screens for photographic or cinematographic projection. J. L. Pech.

CINEMATOGRAPHY.—No. 12,126. Living pictures. R. M. Alexander.

CINEMATOGRAPHY.—No. 12,262. Cameras, cinematograph machines. J. M. Houben.

CINEMATOGRAPHY.—No. 12,327. Cinematograph apparatus. A. Maurice.

CINEMATOGRAPHY.—No. 11,930. Cinematograph machines. W. M. Worman.

COMPLETE SPECIFICATIONS ACCEPTED,

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

CINEMATOGRAPH SHUTTERS.—No. 121,751 (January 7, 1918). According to the invention a shutter for a cinematograph is provided wherein the masking and anti-flicker segment comprises strips of different coloured translucent material. The strips are preferably mounted in a frame, which is adapted in turn to be mounted in a shutter frame on which coloured segments may also be mounted for colour projection, and the colour segments may be arranged to slide behind the masking segments, springs and catches being provided to operate and hold the colour segments, and in such connection the springs may serve automatically to move the segments when a fixed stop is placed in the path of the catches.

As shown in the drawing, *a* is the rim of the shutter frame, *b* the central part, and *c, c* the connecting arms, the whole being formed in one piece, and preferably in thin sheet metal. The masking segment *d* consists of a light metal frame and a series of strips of translucent material, each side of the frame being U-shape in cross section, and the ends of the strips being clamped by the frame.

Certain of the strips are arranged transversely to the other strips, and whilst the strips arranged in one direction are coloured

red, the others are coloured green, so that at all parts of the segment the light has to pass through the two colours.

For fixing the segments to the shutter the outer corners are adapted to fit against studs *e*, whilst the inner part is slotted and caused to engage a T-headed clamping screw *f*. When used, the anti-flicker segments are constructed and fixed in a similar manner. Herbert Shorrocks, 199, Brunswick Street, Chorlton-cum-Medlock, Manchester.

AIRCRAFT CAMERAS.—No. 124,225 (April 20, 1917). The invention comprises improvements in the general construction of aircraft cameras, and provides interchangeable locking means which enables the camera to be operated either manually or by means of

Fig. 1.

an air screw, while preventing the misuse of the camera during such operation, and thus ensuring the correct sequence of operations in changing the plates and resetting the shutter.

The mechanism for changing the plates and setting the shutter comprises a shaft 2, having mounted thereon a handle 1, rigidly connected by set screws 35 with a segmental toothed member 3 engaging with the pinion 4 mounted upon a shaft 36 carrying a pair of larger gear wheels 5, which in turn respectively engage with the racks 6 on the underside of a plate carrier 7.

The handle 1 and the segmental toothed member 3 can be locked by means of a removable locking pin 28 with a reciprocating lever 29 freely mounted on the same shaft 2, and thus recipro-

cate through the lever 29 and a connecting link 30 by a mutilated wheel 17, adapted to be rotated by an airscrew or like means.

If it is desired to reciprocate the handle 1 manually, the pin 28 is removed, thus disconnecting the mutilated wheel 17 from the segmental member 3. The pin 28 can be used to lock the wheel 17 to the casing 50 by passing the pin through the hole 51 in the casing and the hole 52 in the wheel 17, which holes are in register when the wheel is in the position shown in Fig. 3 and disconnected from the airscrew until the exposure trigger is operated.

The plate carrier 7 is arranged to slide in a rectangular framework 8, forming, for convenience, part of the main framework

Fig. 2.

of a camera body. A blind shutter 9 is employed, the operating means being provided for through intermediate gearing between the operating handle 1 and a shutter roller 11. In addition to the roller blind shutter, the camera is provided with a capping flap 12, which is operated during the process of making the exposure.

The mechanism for carrying out the automatic operation of the camera comprises an air screw (not shown) or propeller conveniently driving the changing mechanism through a flexible shaft, allowing of it being placed in any suitable position by the airman.

Fig. 3.

The flexible shaft is coupled to the shaft 13, and a worm 14 in engagement with the worm wheel 15 integral with a pinion 16 engaging with a larger mutilated toothed wheel 17. The larger toothed wheel 17 makes one complete revolution before reaching that portion 21 of the wheel from which the teeth have been removed. The air screw is then free to rotate without actuating the shutter re-setting and plate-changing mechanism until the operator releases the shutter by pressing down the trigger 22. When the mutilated wheel is in this position the leaf spring 33 bears upon a pin 34 mounted thereon, and will move the mutilated wheel 17 to a position which will allow of the pinion wheel 16 engaging with the teeth of the mutilated wheel as soon as the shutter has been operated, thus allowing of the operations of resetting the shutter and changing the plate being carried out.

The mutilated toothed wheel 17 is mounted upon and adapted to rotate a shaft 18 carrying a flanged escapement wheel 19 provided with a slot 43 and stop pin 45. This escapement wheel is adapted to prevent the movement of a pallet 20 except when the escapement wheel reaches a position in which a heel on the pallet registers with the slot 43 in the flange of the wheel 19, and simultaneously the opening 21 in the mutilated wheel 17 is in the position opposite the pinion 16, and consequently out of gear until the exposure trigger is operated. In this position the lever or pallet 20 is allowed free movement, and the exposure or shutter operating trigger 22 can be pushed down, thus actuating the lever

23 by means of the pin 24 shown in dotted lines in Fig. 5 and rotating the lever shaft 25, upon which is rigidly mounted the pallet 20, and consequently turning the pallet to a position in which the heel 44 of the pallet has passed the stop pin 45 and entered the escapement wheel through the slot 43.

When the heel 44 has passed the pin 45, the wheel 19 moves forward under the influence of the leaf spring 33 pressing the pin 34 of the mutilated wheel 17, which is mounted on the same shaft 18 as the escapement wheel 19. The movement of the pallet causes a pin 26 to engage the lever 27 and to release the gearing operating the roller blind 9.

As soon as the wheel 19 has moved forward under the influence

Fig. 4.

of the spring 33, the pallet heel 44 is moved back behind the pin 45 to its first position under the influence of the spring 46, and the resetting of the shutter and change of the plate go on automatically. The rotation of the mutilated wheel 17 by the air

Fig. 5.

screw, and with it the escapement wheel 19, turns the escapement wheel again to the position in which another exposure can be made by the operation of the trigger.

The blind shutter mechanism is wound up from the plate-changing rack wheel shaft 36 through a gear wheel 37 mounted

on the shaft, actuated by a hammer 38 fast on the shaft and a pin 39 mounted on the gear wheel 37, which is loose on the shaft, in engagement with a pinion 40 in one with the shaft carrying the blind roller through the intermediate wheel 41, thus allowing the shutter to be reset. On the other side of the gear wheel 37 a pin 42 is arranged which engages with the pawl lever 27 adapted to lock the mechanism until the operator moves the exposure trigger 22, the lever 27 being operated by a pin 26 at one extremity of the pallet lever 20 as above described.

The capping flap 12 is operated from the pallet 20 through a bell crank lever 31 and connecting rod 32, one end of the connecting rod being connected to the bell crank lever and the other end to the pallet 20.

When the camera is operated mechanically by the handle 1 the locking pin 28 is changed over to lock the mutilated wheel 17 to the casing cover 50.

The removal of the locking pin 28 which locks the handle 1 and the lever 29 mounted on the same shaft 2 to the segment 3 allows of the free movement of the segment under the direct control of the handle 1 through the connecting pin 35, the operation of the plate-changing mechanism being carried out after each exposure by the handle as before described through the medium of the toothed segment and the gearing operating on the plate carrier racks. Frederick Charles Victor Laws, 53, Aldbourne Road, Uxbridge Road, London.

Trade Names and Marks.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

VODETTE.—No. 387,774. Photographs and photographic papers
Albert Drummond Shiels, Thornhill House, Wishaw, Scotland,
photographic artist.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, MAY 31.

Chelsea Photographic Society.—Outing to Mitcham.
Liverpool Amateur Photographic Association.—Outing to Beeston Castle neigh-
bourhood.

MONDAY, JUNE 2.

South London Photographic Society.—"Colouring Bromides." A. Vernon
Goldbold.

TUESDAY, JUNE 3.

Royal Photographic Society.—"Aerial Cameras." Major Laws.
Hackney Photographic Society.—"Chat on Historical Photography." S. Bridgen.
Manchester Amateur Photographic Society.—"Composition for Beginners."
T. M. Shaw.

WEDNESDAY, JUNE 4.

Croydon Camera Club.—"The Importance of Photography in the War."
A. Dordan-Pyke.
Edinburgh Photographic Society.—Fifty-ninth Annual Meeting.

THURSDAY, JUNE 5.

Hampshire House Photographic Society.—Annual General Meeting.

FRIDAY, JUNE 6.

Liverpool Amateur Photographic Association.—Outing to Llanwrhyllyn.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, May 27, Mr. W. B. Ferguson, K.C., in the chair.

Dr. G. H. Rodman delivered a long and most interesting lecture on "Spiders, their Structure and Habits," illustrated extremely fully by natural size photographs of the many known types of spider and by photo-micrographs of their organisms. The very hearty thanks of the audience were accorded to the lecturer.

CROYDON CAMERA CLUB.

AFTER an evening on the spookiest spooks that ever sputtered into being, followed by a washout in the "air and atmosphere art line," last week's fixture came as a welcome relief, the Rev. F. C. Lambert, M.A., F.R.P.S., showing "A Few Simple Experiments." So far as can be remembered, long years have passed since his last visit, and he rather pathetically alluded to himself as being an old man, the only departure from the truth uttered by him during the evening.

He began with a string of apologies, with a final apology thrown in for so many apologies. In photographic circles, he said, it was generally known that what the club did not know was not worth knowing, which included many things known by members not worth knowing.

Out of the slenderest materials he then lectured and demonstrated on various optical, psychological, biological, and other "ogical" matters in most logical fashion, and in doing so struck a novel keynote, which may be described as the antithesis of text-book methods of imparting knowledge. Really instructive were the simple experiments shown, many new to those interested in science, and even the least scientific followed them with obvious attention and interest. Knowledge, he said, only comes from personally-conducted experiments, and if some may regard the observation as rather too sweeping, all will agree that the educative value of careful experiments can hardly be over estimated.

With the alert mentality of youth, the "Croydon manner" never found him at a loss in suitably responding. The blackboard was much used as a recreation ground, and he remarked, if he appeared at all didactic, an early career as a schoolmaster must afford the excuse for restoring any atmosphere of schooldays. "Anyway, you can't spank us," gleefully interrupted the "office boy." "Unfortunately, no," replied the lecturer. Further on, when referring to the primitive ideas on geometry possessed by savages, a member rose and pointedly asked whether allusion was being made to the members of the club. "Not exclusively so," gently said Mr. Lambert, after which he was left in peace.

To give an idea of the way in which subjects were approached, one example relating to "parallax" may be mentioned. Of course, quite an imposing diagram might have been constructed, but he preferred to start with the case of a short and a tall man taking a reading of a barometrical mercury column against a scale set behind the tube, and then, by a simple diagram, showed that the readings might differ. Quite a neat way of conveying the principle involved, and incidentally of removing the impression of one member that it was a contagious disease.

Photographic points touched upon were few, but in the discussion Mr. Sellers, referring to a consideration of the percentage of light reflected by mirrors at various angles to the incident light, said in reflex cameras the usual angle to set the mirror was 45 deg. In a home-made reflex he had employed an angle of 55 deg., and in consequence secured a far brighter image on the focussing screen, and was only sorry he had not carried the idea further. Disregarding a suggestion of a genius that 360 deg. should be ideal, he added that he never employed a surface-silvered mirror, and had never been troubled by double reflections. The lecturer said that had also been his experience. For a delightful exposition on natural magic a most hearty vote of thanks was accorded, tendered to one who has been "the guide, philosopher, and friend of many a young photographer," as the president nicely phrased it.

FORTHCOMING EXHIBITIONS.

September 13 to October 11.—London Salon of Photography. Entries close September 2. Hon. sec., 5a, Pall Mall East, London, 1

TORONTO PHOTOGRAPHIC EXHIBITION.—In reference to the exhibition being arranged by the Toronto Camera Club as part of the Canadian National Exhibition we may supplement our note of a week ago by saying that we have a few entry forms which we shall be glad to send to intending exhibitors, and so save them the delay of communication with Canada. The last day for the receipt of exhibits at Toronto is July 19.

Commercial & Legal Intelligence.

NEW COMPANIES.

COMMERCIAL ART STUDIOS, LTD.—This private company was registered on May 13 with a capital of £1,000 in £1 shares. Objects: Photographers, etc. The subscribers (each with one share) are:—W. Hutchinson, 55, Port Street, S.W., barrister-at-law; R. H. King, Strathspay Regent's Park Road, Finchley, N.5, solicitor. Directors: W. Hutchinson and R. H. King. Registered office, 16, Ludgate Hill, E.C.

WYNNE-HARLEY, LTD.—This private company was registered on May 16 with a capital of £1,000 in £1 shares (300 pref.). Objects: Dealers in photographic and scientific apparatus and materials, publishers, lithographers, etc. The subscribers (each with one share) are:—J. Wynne-Harley, 53-4, Chancery Lane, W.C., commercial illustrator; Jane M. Winterbourne, 53-4, Chancery Lane, W.C., artist; R. Clayton, 53-4, Chancery Lane, W.C., commercial photographer. Directors: J. Wynne-Harley, Jane M. Winterbourne, and R. Clayton.

ST. STEPHEN'S PHOTO-ENGRAVING CO., LTD.—This private company was registered on May 17 with a capital of £5,000 in £1 shares. Objects: Photographic process block makers, designers, engravers, photographers, printers, etc. The subscribers (each with one share) are: H. W. Hawkins, 163, Redland Road, Bristol, newspaper manager; W. J. Robinson, 2, Nevil Road, Bishopston, Bristol, photographer; F. P. Leach, 99, Bishop Road, Bishopston, Bristol, incorporated accountant. First directors: H. W. Hawkins, W. J. Robinson, and F. P. Leach.

UNIVERSAL WOODWORKING CO., LTD.—This private company was registered on May 14 with a capital of £5,000 in £1 shares. Objects: To acquire the business of manufacturers of and dealers in wood and metal furniture, instruments, rules and small goods, carried on by F. H. Shaw at Newhall Hill, Birmingham, under a similar style; also to carry on the business of manufacturers of photographic apparatus and materials, drawing models, compasses, kindergarten goods, calisthenic apparatus, wood dumb-bells, wands, bar-bells, musical skipping-ropes, easels, camp stools, test tube-holders, laboratory sundries, etc. The subscribers (each with 1,000 shares) are:—A. Westwood, 142, Varma Road, Edgbaston, Birmingham, works manager; A. Lawson, 28, Beechwood Road, Bent Lanes, Birmingham, solicitor's clerk. Permanent directors: A. Westwood, and A. Lawson.

News and Notes.

MR. ARCHIE HANDFORD, of 1, Prince's Avenue, Muswell Hill, has on his demobilisation disposed of his business and accepted a position as director with Gordon Chase, Ltd., Bromley and Beckenham.

MESSRS. KENTMERE, LTD., have arranged for a stock of their various papers and cards to be held for them by Mr. Arthur J. C. Lewis, Photographic Works, New Barnet, Herts. Any orders sent to Mr. Lewis will be promptly attended to, and goods sent along same day if order is received reasonably early and is for normal sizes and quantities. Special sizes can always be supplied in the course of a post or two direct from the mills, should they not happen to be kept in stock at the London depot.

GLASGOW PROFESSIONAL PHOTOGRAPHERS' GOLF CLUB.—After a period of suspense of three years this club has again resumed its activities. A meeting was recently held on the Douglas Park Course, Dearsden. During the present month the club is running the first round of the Mains Shield. Its next meeting will be held on June 6. The club will welcome new members, who have no occasion to be expert players. Enquiries should be addressed to the secretary, Mr. John M. Robertson, 3, Scot Street, Sauchiehall Street, Glasgow.

THEATRICAL PHOTOGRAPHY.—Many important points (writes a correspondent) have been gained by actors and actresses engaged under West End managements as a result of the recent "standard contract" agreed upon between actors and managers. The one item

of particular photographic interest is that which decrees that "photographic calls shall be treated as rehearsals"; and as another item states that any artist receiving less than £10 per week shall be paid 10s. for each rehearsal, it means that ballet girls and many others, when attending a studio officially, will be paid by the management.

PICTORIAL PHOTOGRAPHY IN AMERICA.—An annual publication to be issued with this title is announced as making its first appearance about November of the present year. The promoters, in acknowledging the representation of British pictorial work in "Photograms of the Year," say that it is their intention to make the volume in no respect inferior to the British repository of current photographic art. The publication will be in the charge of an editorial board consisting of Messrs. Clarence H. White, W. H. Porterfield, John Paul Edwards and Dwight A. Davis. Prints to be submitted for inclusion in the volume should be sent to the Board, 122, East 17th Street, New York, to arrive not later than July 1. The volume is to be published by Messrs. Tennant and Ward, 103, Park Avenue, New York, at the price of 2 dols. 50.

PHOTOGRAPHERS' ASSOCIATION OF AMERICA.—This association of professional photographers is again holding its summer conference (the first in three years) at Cedar Point, on Lake Erie, near Cleveland. The meeting is of more than ordinary interest, since it signals the fiftieth anniversary of the first meeting of professional photographers in the United States. A large programme of demonstrations and lectures has been arranged; there will be an exhibition of portraiture by leading professional photographers and a great representation of the manufacturers. The conference will last from July 28 to August 2, and we are glad to pass on from the general secretary, Mr. J. C. Abel, a cordial invitation to any photographer to take part in the conference. Any communications for the general secretary should be addressed to him at 421, Caxton Building, Cleveland, Ohio.

Correspondence.

. *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

. *We do not undertake responsibility for the opinions expressed by our correspondents.*

MASKING IN ENLARGING.

To the Editors.

Gentlemen,—I would like to endorse the remarks of "Practicus" in your issue of the 9th inst. *re* enlarging with and without masks on the negatives. The two methods put forward by your contributor "Thermit" some weeks ago are also noteworthy; the idea of sizing up (on a white paper, I take it) on a black easel is novel, and certainly has its merits.—Yours faithfully,

H. T.

REVERSAL IN TANK DEVELOPMENT.

To the Editors.

Gentlemen,—Referring to your note *re* reversal in the current issue of the "B.J.," I am sending you an old negative from my accumulation of curiosities, which may, perhaps, throw some light on this matter. The example sent, as you will observe, shows a negative at one end, which merges into a positive at the other. The cause of this reversal was light-leakage in the dark slide.

Another form of quasi reversal is occasionally met where the shadow detail of the negative portion appears, as it were, bleached, and makes a partial positive, unmistakably different from that caused by the action of light. This occurs only when the developer is of the metol-hydroquinone type and lacking in sulphite, the presence of quinone in the developer presumably being the inciting cause in such instances.—Yours very truly,

E. A. MAITLAND.

THE SYSTEMATIC TONING OF P.O.P.

To the Editors.

Gentlemen,—I am pleased to learn from your pages (p. 263, of last week's issue) that Rajar, Ltd., are making an effort to revive the practice of toning P.O.P. systematically, but, if I mistake not, it was Mr. Wilson, of the Paget Company, who originated the system, not the Kodak Co. According to my reference book the plan—with fable—was first published in a booklet issued by the Watford firm in the year 1894.

The original table was not so simple as that given by Rajar, Ltd., and it was because of its complicated nature that the average photographer did not take so kindly to it as he should have done. I may perhaps recall the fact that the (1894) toning bath was as follows: Water, 8 ozs.; ammonium sulphocyanide 12 grs.; gold chloride 1 gr. Sixteen minims of this bath were required to tone a square inch of print, or, in other words, 1 oz. of the toning bath was required for a full half-plate print.

The simplicity of the Rajar table has much to recommend it, and it is one that should—and probably will—find its way into works of reference.

The table, like the Paget table, is excellent for the P.O.P. made by the firm advocating it, but I am not so sure that other makes of paper work at their best with either of them, because of the varying natures of P.O.P.—Yours faithfully,
L. T. W.

ASSISTANTS' WAGES.

To the Editors.

Gentlemen,—Could you spare the space in the "Correspondence" column of the "B.J." to publish the following remarks on the wages offered to assistants by the professional photographers at the present time?

Looking through the "Situations Vacant" column one cannot fail to notice one or two of such advertisements advertising for operator and retoucher, bromide printer and enlarger, etc., requiring a thoroughly competent, capable man for the inadequate sum of £2 per week. How does an employer expect any man to exist on that, especially in London, where he is compelled to pay at least £1 10s. for decent lodgings, apart from tube and bus fares, to dress respectably for the position of operator, considering that at the present time £2 is only equivalent to 16s. or 17s. in 1913? Thousands of men like myself enlisted early in the war, when the public were patriotic. Employers promised the men their situations would be kept for them. Now the latter have come back to find girls and the men who have "swung the lead" occupying their berth at a mere existing salary, and taken on temporarily; the employers now refuse to re-engage their pre-war assistants, as they are getting the work done by cheap labour.

Many clever and competent men have re-engaged in various branches of the Army and Air Force, for the simple reason that, though not liking a military life, they are better paid, besides being provided with food and clothing, preferring to be so employed rather than add one more to the long queues often seen outside the Labour Exchanges.

In cases where girls are compelled to earn their own living, when doing a man's work they should receive the same rate of pay, not, as often is the case, 10s. or 15s. a week less. Unfortunately, there are plenty of "war products" on the labour market, amateurs of pre-war days with other trades on their hands, who were called up for service and managed to get into photographic sections of the R.A.F., and now consider photography an easy way of making a living. Their knowledge is usually limited to the plain, straightforward work learnt during their Army career; yet they are now preventing numerous competent men from obtaining a respectable post.

I fully agree with a high-class photographic artist who some time ago, when advertising, inserted: "No war products need apply," and was criticised in "John Bull." Evidently Mr. Bottomley does not quite understand what harm the war-product has done to the assistant who has served his time to the trade only to find it usurped by such. Hoping this may help some to realize what many assistants are feeling sore about.—I am, yours faithfully,
AN ASSISTANT.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

S. N.—If the deposit has a crystalline appearance, it probably consists of hypo, which is hardly likely to be present in such a quantity. If fluffy, it is mildew, and for this we fear you can do little, except to wash it off.

F. M.—We expect the marks are metres, which can be reckoned sufficiently near for practical purposes as yards. If you convert into feet you will see that the scale approximately corresponds with that on British cameras.

P. L.—An iodine bleach for sepia toning consists of a solution of, say, $\frac{1}{2}$ oz. iodine and $1\frac{1}{2}$ ozs. potassium iodide in 20 ozs. of water. It is a very expensive bleach, and has no advantages over the mixture of ferricyanide and bromide. We do not know of any sulphite sepia toning bath.

E. R.—If you move a business to a new quarter, we are practically certain that such would be regarded as the establishment of a new retail business, and you would require to apply for a licence to the office which deals with the district to which the business is being transferred. We published particulars of these offices in the "British Journal" of May 9.

W. M.—It is possible that the metallic spots are caused by impurities in the alum. You may have bought it from the same dealer all the time, but he may not have been buying it from the same firm. The most common cause of these spots is through iron rust in the wash-water, in which case they can be prevented by tying a flannel filter over the tap.

F. C.—Certainly, you are eligible to apply for a licence to start a new retail business. You do not say where it is proposed to establish the business, but you will be able to tell from the enclosed cutting the office to which to apply. You must apply to the office dealing with the district where the business is to be established, which may not be the same district as that where you are now living.

L. A. N.—To produce a mezzotint a copper plate is first finely grained all over by mechanical means. If an impression were taken it would be an even black all over. The artist produces high-lights and half-tones by scraping and burnishing the copper where necessary. The surface usually receives a final coating of steel to save wear. Colour mezzotints are produced by inking the one plate locally; this requires great skill.

M. F.—The particulars of the lens are very scanty, but as it is described as a doublet, it is probably quite an old Ross doublet of aperture probably $f/8$. These are very excellent lenses in their way, and while not of the covering power of an anastigmat, give excellent definition over a somewhat narrower angle. For a whole-plate we should say the focus should be 10 or 12 ins. This, no doubt, you can easily measure.

M. N.—No need to apply for a licence. If the business is carried on in any name other than your own it is necessary to register it and to state your real name on stationery. The only means of avoiding this necessity is to convert the business into a private

- limited company, but even in this case, if you are a director of the company, a further Act directs that your name shall appear upon the stationery.
- R. H.—The size you name is not a standard Continental size, and certainly not a British. Possibly the dark-slides take plates of a different size from the focussing screen. We are sorry we are not able to identify the maker of the camera from the mark you mention, which very likely is only the registered mark of some French dealer. Perhaps you might get the information from our French contemporary, "Photo-Revue," 118, Rue d'Assas, Paris.
- BUSINESS REGISTRATION.**—Could you tell me if the Registration of Business Names Act requires one to register every year? I believe I saw in the "B.J." a week or so back something to this effect, but cannot trace it. Shall be very much obliged if you would kindly give me the information.—A. A.
- Annual registration is not necessary, and no further fee is required unless any alteration is made in the firm or title of the firm.
- CLERICS.**—Unfortunately, there are no methods at all exact for exposure of such subjects. The best course is to judge the exposure of the interior by means of a Wynne or Watkins meter used inside the building and then to expose through the blue, green, and red filters in accordance with the multiplying ratio given by Messrs. Wratten for their filters used with their plates. We do not think you would get any satisfactory indications by testing the light outside.
- B. E.—A 10-in. focus is about the right length. The Dallmeyer A of 250 mm. would be a good lens, but you can take your choice among portrait lenses of $f/4$ or preferably $f/3$ aperture. Probably your best course would be to state your requirements to a second-hand dealer, and ask what lenses corresponding with them they could offer you. It would perhaps save a good deal as compared with buying new, even if you can get new lenses, which is very doubtful.
- W. G. A.—Candles are made of what is practically paraffin wax. The two materials may be used for the same purpose. You can make your white enamel black by stirring in the finest lampblack, although it is doubtful if you will make such a good job of it as buying black enamel. The grain weight is the same in apothecaries and avoidupois. Get the finest carborundum powder from Messrs. George Adams, 255, High Holborn, W.C.2, if your regular ironmonger cannot supply you. By using a small bit of glass as a rubber you can grind a very fine grain on glass in any size.
- W. W.—The greeting postcards are machine printed on rotary machines from single negatives which are made by photographing a given design with the photograph inserted in it. For example, in the case of the specimen you send, the floral and greeting portion would have a circular aperture cut in it and the photograph placed behind it in making the copy negative. Of course, on the small scale, double printing could be used and design negatives for this purpose are supplied by the dealers, though not, so far as we know, with greeting lettering on them. One firm which makes a speciality of these border negatives is Artista, 5, Rue de Montfaucon, Paris, VIe.
- M. J.—It is a little difficult to separate the different disputes related in your letter, but in the first place a reasonable charge for the job mentioned in the first paragraph would be 10s. plus out-of-pocket expenses for taking the negative and supplying one print. Subsequent prints, say, at 4s. a dozen. As regards the cancelled order, it seems that you accepted the cancellation and therefore we see no escape for you from the charge which the engravers have made. Regarding the claim that A ordered no photographs of the mill, but a block, surely the order is established by his acceptance of delivery of the dozen prints. If he has accepted them, then it is clear that the block is a separate transaction.
- B. A. E.—Your case is met in a measure by Section 2, according to which any fair dealing with any work for the purposes of private study, research, criticism, review, or newspaper summary is held to be not an infringement of copyright. There has not been a case in the Courts on this point, but it is conceivable that the making and exhibition of a lantern-slide of a work, accompanying a lecture on the subject, would come within "criticism." As a matter of fact, lecturers copy copyright originals rather freely, obtaining permission if they can discover the owner of the right. Damage to

such rights is so small that we have never heard of any difficulties arising between a lecturer who has used the work and the owner of the rights in it.

- B. B.—(1) With all deference to the writer of the article, our opinion is that for anyone who is enlarging negatives as large as whole-plate a system of illumination by reflected light is preferable to a direct one. Such a system is commercially embodied in an apparatus of Messrs. Marion, the principle of which is that of a white box, in the front of which the negative is placed and strongly illuminated by half-watt lamps arranged at either end. This is much better for even illumination over a large negative. In the case of that suggested, unless you use very thick diffusers, such as opal, and a very high power of half-watt, say, 3,000 c.p., placed some considerable distance behind the opal diffusing screen, you would not get even illumination. And then, of course, you would cut down the power of the light enormously.
- (2) "Photography of To-day," by Chapman Jones, is altogether a different book from the "Science and Practice," and does not replace it. No doubt Messrs. Ibbie will have "Science and Practice" in print again before long.
- B. N.—As regards the addition of formalin to the developer, it is not a good plan for the reason that formalin forms compounds with sulphite which act somewhat in the nature of alkali, and therefore disturb the balance of the developer. You had much better use a fixing-hardening bath of alum, sulphite, hypo, and acid; or, if you want an extra degree of hardening, you can choose from formulæ issued for the tropics. Avoidance of all handling of the films during development is a very great factor in avoiding frilling. We suppose you adopt the usual plan of developing the bands of film suspended in a tank. The Kodak Company has worked out this system very fully for the use of dealers, and supplies the tanks and formulæ for the developer. The usual combination is pyro, metol, and hydroquinone. With regard to printing quickly, presumably on gaslight paper, you must have a box printer, or you will waste an enormous amount of time. With any of the box printers you can arrange stops for the masks, so that very little time is lost in laying down the negatives and paper. The usual plan is to print from the film negative whilst still in one piece, and not to cut up the negative until the order is at the very last stage of return to the customer.

Line Advertisements.

Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.
(No reduction for a series.)					

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.
Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.
Displayed Adv'ts should reach the Publishers on Monday morning.
The insertion of an Advertisement in any definite issue cannot be guaranteed.

ELEVENTH YEAR.

SUMMARY

Mr. Colin M. Williamson describes the camera designed by him during the war for aerial photography, in particular the F type for the exposure of a band of film and the lili type for plates. (P. 309.)

Instruction in a very simple method of masking prints having printed-in tinted borders is given in an illustrated article on page 314.

The practical methods of chief importance in the taking and printing of stereoscopic pictures are the subject of the second of the series of articles on this branch of photography. (P. 307.)

An article by Mr. J. McIntosh gives instruction in the making of light-filters for panchromatic plates and in the testing of them for their effect in the monochrome rendering of various descriptions of colour subject. (P. 317.)

The use of a high-power half-watt lamp for enlarging on gaslight paper is the subject of an illustrated note on page 319.

The weekly article by "Practitioner" has for its subject the portraiture of children. (P. 312.)

The glazing of gelatine prints by stripping is the subject of some practical notes by Mr. C. Brangwin Barnes, who deals particularly with the avoidance of surface markings on prints glazed in this way. (P. 316.)

Working details of the preparation and use of gum bichromate paper for multiple printing are given by a Canadian contributor, Mr. Charles Macnamara. (P. 320.)

In "Photo-Mechanical Notes" one paragraph describes the making of photo-engraved blocks of lettering to show a shadow effect. (P. 322.)

A light-tight box in the dark-room for unexposed plates is a labour-saving accessory which should be more widely used. (P. 306.)

The want of rendering of delicate tones in light portrait draperies is often not ascribed to its real cause—viz., halation due to the use of an unbacked plate. (P. 306.)

The profile portrait is a style which, with a suitable sitter, lends itself to novel and attractive effects. (P. 306.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.
Some notes define the present position of colour photographic processes and indicate some possible directions of progress. (P. 21.)

Mr. Bertram E. Havelock contributes an article on the effect of the light-filter on focus in Autochrome photography, detailing methods of avoiding its effects in practice. (P. 22.)

A portable apparatus for the viewing of colour transparencies has been designed by Mr. Arthur E. Morton. (P. 23.)

Some practical hints on the Paget process appear on page 24.

A note on page 24 provides a guide to the text-books on colour photography.

EX-CATHEDRA.

Profile Portraits. We are inclined to think that many photographers do not sufficiently realise the possibilities of profile portraits, while others make a practice of including one in every set of proofs when the features of the sitter render this possible. Very often an uninteresting face with quite irregular features gives a good side view, and if it happens that the outline of the nose or chin is not altogether classical it is much more easy to effect the necessary alterations in a profile than in a full-face pose. There are a few points to be observed, an important one being that the outline of the features should be perfectly sharp. It is well sometimes to have parts of the figure melt into the background, but noses do not come into this category. It is desirable to have considerable contrast between the face and background, the former being in semi-shadow for a white background or in full contrast for a dark one. Some good hints can be obtained by studying the beautiful portrait medallions of Wedgwood which are reliefs in white "biscuit" porcelain upon a blue, green, or black foundation. These effects might be almost exactly reproduced in carbon, since some of the Autotype tissues very nearly match the Wedgwood colours. As the ear is a prominent feature in this class of pose, one must be careful not to exaggerate its size: to avoid this, as long a focus lens as possible should be used. Profiles are admittedly not good portraits, but undoubtedly they have considerable pictorial charm, and are, therefore, appreciated by the more cultivated class of sitter.

Backed Plates for Portraiture. The majority of photographers have a way of regarding backed plates as necessary only for such subjects as interiors which include windows, and occasionally outdoor subjects which have to be taken against the light. It is true that such subjects very plainly demonstrate the necessity for backing, but there are many portraits which suffer badly from halation without its being recognised. Certainly when a very dark dress is opposed to a white background, or white trimmings occur on a black dress, halation is usually very evident, but we may have a subject which is entirely composed of light tones in which all the more delicate gradations are lost from the same cause without knowing it, attributing it to local over-exposure. Every portraitist appreciates the difficulty of preserving the delicate half tones in a bridal dress while getting sufficient exposure for the face, and various dodges in lighting, exposure, and development are resorted to in order to get a decent result. If, however, backed plates are used, quite straightforward methods may be employed and perfect gradation obtained. It is well worth trying the experiment of using both backed and unbacked plates upon such subjects and comparing the results. With any great in-

crease of rapidity in the emulsion there is usually an increase in the transparency of the film of bromide of silver, and this naturally tends to favour halation. For the benefit of those who have not studied the matter, we may point out that a great proportion of the light which passes through the film is reflected at a slight angle from the inner back surface of the glass, causing more or less fog at a little distance from the high-light which has caused it. The position of this reflection is probably in one of the delicate shadows the true value of which is destroyed, and this being repeated in a hundred places, the result is a general flattening of the image. We have found some photographers partly obviate this by using a slower plate which has a more opaque film, but a better effect may be produced upon a rapid plate if it is properly backed. Backing is a very easy process if the materials are kept in constant readiness in the dark-room; a few seconds then suffices to apply the colour, and there is no need to wait for the coating to dry. A plate is none the worse for any purpose because it is backed, but those who object to the extra cost of backed plates can back their own when needed at a cost of less than a penny for a dozen half-plates.

* * *

A Dark-Room Plate-Box. In these busy days, when one would expect to find every labour-saving device taken advantage of, it is surprising to find that few dark-rooms are properly equipped for the rapid and safe handling of plates before exposure and development. It is quite the usual thing to find that the plates are filled in direct from the maker's boxes, and there is a great loss of time in opening and closing these, besides a risk of leaving the plates exposed to be spoiled if the light is turned up. It is a much better plan to provide a box, say, 6 x 8 x 8, with a well-fitting lid into which three or four dozen half-plates can be transferred, all facing one way and standing upon their edges. For other sizes boxes proportionately larger will be needed, and all should have the lid so made that either by means of a spring or gravity it will shut automatically. Such boxes have been fitted with an electric alarm which rang as long as the box lid was open, but this seems unnecessary if the lid closes automatically. To receive exposed plates there is nothing better than a cupboard conveniently placed with regard to the sink, with partitions to receive the various sizes. The plates are again stacked on edge in the order of exposure. The front edge of this cupboard should not be vertical, but the top further back than the bottom. The lid should be hinged at the top and weighted with a leaden strip at the bottom. This will keep it tightly closed. Of course, there must be a deep rim or flange all round the door, and the inside of both boxes and cupboard should be dead black.

* * *

Short-Focus Lenses. In the minds of many photographers an impression exists that short-focus lenses necessarily give exaggerated perspective, and that nothing can be done to minimise the defect. If we say that a short studio is to blame we should be nearer the truth, for the fact is that perspective depends entirely upon the point of view, and if this is sufficiently distant the rendering will be agreeable, no matter what the focus of the lens may be. This may be of comfort to those who do not wish to have to be limited in the choice of poses by the fact that they do not possess a long-focus lens. One of the most difficult poses to render without exaggerated proportions is a seated figure of a man with the knees crossed, yet it is often very characteristic of the sitter, and if skilfully managed makes an attractive picture. One of our correspondents, whose largest lens is a 3 B with a focal length of eleven inches, gets over the difficulty by using it at a distance of

twenty feet, and disregarding the size of the figure in the original negative. As a matter of fact this is only of carte de visite size, and is subsequently enlarged to whatever dimensions may be required. If only cabinets are wanted they are as sharp as most direct pictures, and a 24 by 18 does not give any impression of fuzziness; in fact, the general definition is far better than if a direct negative of this size had been taken. A little care should be given to the selection of plates for this method of working, as if very rapid emulsions are used the grain is likely to be too much in evidence, but by using a slower plate sufficiently fine definition will be obtained. No fear of long exposures need be entertained, as at this distance there is excellent depth even at large apertures.

NEGATIVE DEVELOPMENT.

It is as impossible to lay down any hard and fast rules for development as it would be to prescribe the quantity of paint and the method of application to be employed in painting a picture, for there is no standard for the quality of a negative, this depending entirely upon the taste and skill of the producer. It is, of course, largely dependent upon exposure, and this cannot be determined even by the most perfect meter, for a theoretically correct exposure which accurately rendered the tonal values of the original would in many cases not give the most pleasing result. As a matter of fact, most satisfactory negatives receive a considerably longer exposure than theory would demand, and development is not carried on until all the affected silver salts are reduced to the metallic state.

Skilfully employed one developing material will give much the same effect as another; that is to say, if we accept the dictum that a perfect negative consists of pure silver embedded in pure, clean gelatine. Pyro is, perhaps, an exception, for here we have a silver image plus a thin image consisting of oxidised pyro, but if the latter be removed by means of an acid-clearing solution the pyro-developed image is no different from any other. The presence of the yellowish pyro image which exists even in an apparently stainless negative adds appreciably to the printing density, so that a thinnish pyro negative will give as bright a print as a much stronger one developed with a non-staining developer such as amidol. That quality is not dependent upon colour is proved by the printing value of wet-collodion negatives, which is unsurpassed. It is a matter of surprise to the modern printer when he is handed a good wet-collodion negative to find what softness and brilliancy can be obtained from a plate which is quite different from any which he is in the habit of handling. Nevertheless, a good pyro negative is highly satisfactory, no matter what class of image is desired, and pyro will doubtless remain a prime favourite with those photographers who think of their prints rather than of their fingers.

There are many factors (not in the Watkins sense) which influence development, the principal being time, temperature, and strength of solution. The greatest degree of control over the character of the image can be obtained by variations in the time the plate is submitted to the action of the developer. Anyone can prove this for himself by cutting a plate exposed upon an evenly illuminated subject into three strips, placing them together in a normal developer and developing for two, four, and eight minutes respectively. Upon fixing, it will be found that there is little difference in the amount of detail visible, but that there is a great difference in the contrasts in the various sections, the first being decidedly soft if not flat, the second of average quality, and the third very vigorous and likely to give a chalky print. It should be generally

known that density can be obtained in less time with a slow or ordinary plate than with a rapid one, and that has given rise to the idea that rapid plates are not capable of giving dense negatives. The experiment just mentioned will prove that this idea is an erroneous one. Other factors than speed of plate may tend to slowness in this respect; for example, a plate made with a hardened film for tropical use is naturally less permeable to the developer than one with a softer film, and at a given temperature will require a longer time to give the same density.

Temperature affects density inasmuch as the action of the developer is accelerated by heat, and that therefore a shorter time is needed to obtain any given strength of image. This is recognised by most operators who warm the developer in winter, and cool it by the addition of ice in summer if the temperature is much above the normal. We have seen a portrait photographer with a large number of normally exposed plates which developed so quickly in a temperature of 80 deg. Fahr. that excessive density was obtained in less than two minutes; on cooling the solution to 60 deg. ordinary density came in three minutes, with no blocking of the high-lights.

The degree of concentration of the developer is another important factor which is not so generally recognised as it should be, although tank development has taught us much in this direction. It is a common practice to employ a diluted developer for subjects having strong contrasts, and soft images are thereby obtained, but this is only a question of time. If we use a solution of Azol one part and water fifteen parts we shall obtain a certain degree of density in five minutes, but with a similar exposure using Azol one part and water sixty parts we shall require at least twenty minutes to obtain identically the same result. So far we believe there has been no definite ratio established between the degree of dilution and the time of development required to give equal densities which will hold good with all developers, so that no general rule can be given.

Various developing agents behave differently with plates of the same brand which have received equal exposures; for example, metol causes the image to appear rapidly, but it takes a considerable time to obtain full density. Thus, it has been assumed that metol used alone gives a very thin image. This is not necessarily so, as it is possible to develop a strong black-and-white negative if sufficient time be given. On the other hand, hydroquinone gives density very readily with very clear shadows, hence the popularity of a mixture of these two reagents.

The addition of a soluble bromide has the same effect with all developers, namely, to steepen the scale or increase the contrasts during the earlier stage of development. For this reason it should be put into the solution before pouring upon the plate if over-exposure is suspected. It is of little avail to add it after the image has appeared, and in any case if the image be developed "right out," that is to say until all the reducible bromide is reduced, there will be little difference whether bromide be used or not. As, however, this is rarely done, bromide is rightly esteemed as being a valuable aid in cases of over-exposure.

Effects produced by variations in the proportions of the developer are mainly due to the time factor. For instance, increasing the proportion of soda hastens development, but does not give any increase of detail, as is generally imagined. Hence, there is nothing to be said for the old practice of "working up" a plate by successive doses of one ingredient or other. This was quite an article of faith some years ago, but few hold by it now. It probably originated when ammonia was the alkali almost exclusively used. This is naturally extremely volatile, and soon

evaporated from the developer; on the addition of more ammonia the action was renewed, but with the fixed alkalies, such as the carbonates of soda and potash, this is not the case.

With some developers, pyro particularly, the time the solution is kept before using has a considerable effect upon its efficiency. If a freshly made 10 per cent. pyro solution prepared with sulphite and metabisulphite be tested against a similar solution which has been made for three months and kept in a half-filled bottle, the latter will be found appreciably weaker, though there may be little change in colour. Solutions of less strength deteriorate more quickly; the favourite strength of one ounce of pyro to eighty ounces goes off very soon, even a week showing a considerable change.

STEREOSCOPIC PHOTOGRAPHY.

II.—PRACTICAL HINTS.

As the eyes are generally about $2\frac{1}{2}$ to $2\frac{3}{4}$ inches apart (from pupil to pupil) it follows that the views depicted by the lens upon each retina differ from each other exactly as would the views in a double camera fitted with two lenses separated horizontally by a distance of about $2\frac{1}{2}$ to $2\frac{3}{4}$ inches. Two photographs of an object produced in such a camera would, in fact, correspond exactly with the two retinal images produced when we look at that object, and whatever mental impression is associated with the dual retinal pictures would be equally associated with their photographic counterparts, provided that we view each simultaneously with the eye corresponding to its point of view.

If we only bear this simple correspondence in mind in connection with stereoscopic practice we shall not fail to produce results which will be quite satisfactory, and will appeal immediately to anyone who has normal sight. If, on the other hand, we alter the conditions by placing the two photographs, as is so frequently done, at a distance exceeding the $2\frac{1}{2}$ inches limit, many people with perfectly normal sight will find it difficult to make the two images blend in the stereoscope, and will only get the effect after waiting for some little time for the eyes to accommodate themselves in the singular way in which they will when conditions are a little outside the appropriate. The temptation to place the prints at a 3-inch interval is often stimulated by the fact that by so doing a wider field of view can be covered. It will be shown, however, presently, when we come to speak of trimming, that there is a much better way of securing the maximum of field than by forcing the eyes to accept an abnormal separation of the images.

No great objection need be taken to the separation of the stereoscopic camera lenses by as much as 3 inches. This involves no strain as long as the resulting photographs are mounted at the right distance apart. The reason of this will be apparent when we come to deal with "giant vision" stereograms. But with regard to the position of the prints themselves even $2\frac{1}{2}$ inches is a little wider than the extreme separation should be. For perfect effects the range of separation should vary from $2\frac{1}{2}$ inches for foreground objects to $2\frac{3}{4}$ inches for objects in the extreme distance, and if this rule is observed the eyes will immediately accommodate themselves, and the picture will always show itself in full relief at first glance in the stereoscope.

With regard to the stereoscopic camera there are many ingenious devices by which an ordinary camera with a single lens may be made to do duty in place of a pair of twin lenses. The double pair of mirrors devised by Theodore Brown is one of the most ingenious of these devices, and no doubt excellent work can be done in that way. The same inventor has other ways of making a single lens

Stereogram from a pinhole negative. By C. E. B.

answer for stereoscopic work. But at the same time these substitutes have drawbacks, and must only take second place as compared with a properly designed stereoscopic camera with twin lenses. The chief desideratum of such a camera is exact equality of lenses in focus, and this essential point is, of course, strictly attended to by all good makers, who also take care that perfect alignment is secured, and that other details of construction are properly regarded. Special plates $6\frac{1}{2}$ inches by $4\frac{1}{4}$ inches are made, but a plate 5 inches by 7 inches is excellent if the camera will admit of it. For stereograms of objects in which there is no movement an ordinary quarter-plate camera may perfectly well be used, the two pictures being taken successively from view-points varied by an appropriate separation according to the distance of the object. There is, indeed, an advantage here over the twin-lens camera. In the first place, the distance of separation of the two view-points is variable ad lib.; and secondly, the same lens being used, there must be actual identity of size and of focus. The drawbacks in connection with successive pictures are that, of course, this plan precludes any movement, and it also requires no variation of lighting, a factor not always easy to secure in the case of landscape work when the sky is not cloudless. Nor must any change, however minute, occur in the scene depicted between the two exposures.

Perhaps the most perfect stereograms as regards atmosphere and tone value are those produced with the pinhole camera. A monograph by Rev. J. B. Thomson in the "Photo Miniature" series (No. 27 of 1901) gives admirable instructions as to the pinhole stereoscopic camera, which is easily constructed out of an ordinary half-plate box with a central partition added. For landscape and architectural work this very simple apparatus can, in the matter of artistic and natural effects, defy the competition of the best lenses within the limitations of the instrument, but these limitations are, of course, somewhat hampering. The exposure

is long, and living or moving objects are quite outside the scope of the pinhole camera. Focussing is not required, but on the other hand the correct placing of the picture in the absence of lens and ground glass is a little troublesome, though with the aid of guiding view-lines on the top and side of camera the difficulty is got over. If the converted plate box is used as a camera a changing bag is necessary in default of the magazine for dark slides.

A point that needs close attention in stereoscopic photography is the choice of subject. For the best effects this should be one in which the receding dimension is conspicuous. Many a scene which for that very reason is not well suited for an ordinary photographic composition has a special charm in the stereoscope. A row of house fronts facing the camera is obviously not the sort of view that commends itself for stereo effects, but a peep along the same row from an appropriate point of view may be just the kind of glimpse that lends itself for stereoscopic treatment. An avenue of trees, an arcade, a sheet of water with reflections, a crowd of people, a well-lighted group of statuary, or a single statue are typical stereoscopic subjects. Also small objects, many of which would hardly repay the photographer with the single lens camera—a teasel (*dipsacus*), a dandelion seed globe, an orchid, a Japanese toy, and many another unconsidered trifle will become transformed into wonderful visions of beauty when skilfully stereographed.

With regard to the negative, if any error is permissible it must be on the side of over-exposure. An under-exposed photograph never makes a good stereogram, though one that is flat to a fault as an ordinary photograph is often perfect as a stereoscopic view. Detail is the essential; flatness is got rid of by the stereoscope itself. Matt surface prints are not to be commended: the magnifying power of the stereoscope lenses enlarges the fibres of the paper too much. It is better to use a glossy paper; in fact, whatever paper will bring out the greatest abundance of detail.

Assuming that the two pictures are on one plate, it must never be forgotten that the print must be divided and the two halves transposed. The necessity for this is not clearly understood by many workers. The explanation is this. In the camera each lens inverts its image. If we were to keep the print upside down and after dividing it we were to invert each picture separately they would require no transposition, but if (as is naturally the case) we turn the whole print round before we divide it we have already placed the right-hand picture on the left and the left on the right, so that we must transpose to correct this. The simplest way of ensuring correct mounting is to write in pencil R. and L. on the actual right and left sides of the back of the print before dividing it. The two halves will then be transposed in the correct way by attending to these letters when mounting.

It is important that the mounts should not curl, but be very flat, and if any difficulty arises as to this it is best to mount a corresponding strip of plain paper on the other side of the card to avoid warping. This must, of course, be done at the time of mounting, not later.

As to the position of the two pictures no corresponding points even in the extreme distance should be more than $2\frac{1}{2}$ inches apart. A little less than this is advisable, and the foreground objects may have a separation of a little less than $2\frac{1}{2}$ inches. An average of $2\frac{1}{2}$ inches is, in fact, the most comfortable separation distance for a stereogram.

One further point is often entirely overlooked, though it is of great importance. One should always see that the

left-hand print includes more of the right-hand part of the scene than the right-hand print, and one should cut the right-hand print so that it includes a corresponding extra part of the scene on the left, which does not appear in the left-hand print. This will increase the total width of the view considerably, and at the same time will throw the stereogram back behind the plane of the card when it is viewed. If, on the contrary, more of the left side is seen in the left picture and more of the right side in the right picture, the result is a weird effect of a scene floating above the plane of the card, like a picture that has come out in front of its frame. The common idea that the lateral limits of the two pictures should be identical is entirely erroneous, and is very disadvantageous, as it contracts the field of the view to a minimum.

For special subjects suited to the use of a single-lens camera and successive photographs it is worth while, if a large number of prints are required, to take two half-plate views at a view-point separation of 4 to 6 inches, according to the subject. Prints from these are mounted side by side and then a reduced negative made of the pair, brought down to such a size as to bring the corresponding points to a lateral separation of about $2\frac{1}{2}$ inches. This negative can then be masked appropriately, and the prints from it will be complete stereograms requiring no dividing or transposing. Pinhole stereograms, of course, benefit materially by this reduction method, and the above plan applies especially to them.

C. E. B.

THE EVOLUTION OF AERIAL CAMERAS DURING THE WAR.

[Among the designers and constructors of cameras used during the war for aerial photography none perhaps deserves greater credit than Mr. Colin M. Williamson, head of the Williamson Kinematograph Company. Certain highly efficient features of aerial cameras were originated by him, and indeed it may be said that one conception of his, originated in the relatively early stages of the war, provided a means by which subsequent types of aerial camera performed, in the hands of the non-photographic airman, the tremendous services in mapping enemy territory and works which are now familiar history. At our request Mr. Williamson has written the following few notes from which, in conjunction with what has just been said, the value of his work may be judged.—Eds. "B.J."]

Before the war the only successful photographs taken from the air were made from lighter-than-air machines for the simple reason that aeroplanes of that time were too uncertain in their behaviour and too shaky to allow of any satisfactory definition at a less speed of exposure than about 1/500th of a second. However, at the outbreak of hostilities observers' pluck rose to the occasion, and as a result some truly amazing photographs were obtained by hanging over the side with a glorified Kodak. As an absorber or damper of the intense vibration of these early machines—and, in fact, of later models of aircraft—probably the human body has the advantage over any mechanical device, such as an air-cushion, sponge rubber, or the various forms of suspension. The considerable vogue enjoyed by the hand-held camera and its repeated return to popularity may be explained by this fact. Thereafter the trend of design can be traced by the development of the aeroplane itself and to the successive changes in the conditions of aerial warfare.

It was soon found that the ordinary double-back plateholder was unsuitable and very difficult to handle in the air, with the result that an exceedingly simple but ingenious form of changing magazine for the plates was devised. In its original and simplest form—that known as the C model—it consisted of a platform below which, pointing downwards to the earth, was the lens tube with the focal-plane shutter mounted centrally immediately below the platform. Immediately above, mouth

downwards was the magazine of unexposed plates, whilst below the platform, to one side of the lens tube and mouth upwards, was the magazine to receive the exposed plates, its open mouth so to speak, having a casing over it to provide a light-tight passage along which the plate was guided from the upper magazine to the lower.

It may be said that this model of camera represented the ideas of designers for the Air Force in 1915; it was introduced for the use of airmen early in 1916. At this time—and, indeed, almost to the period of the Armistice—the Air Force, no doubt for good reasons, was pledged to the use of plates, although it can be readily understood that a flexible sensitive material like celluloid film is much more amenable to handling in a camera which is used by a man having the very slightest acquaintance with photographic apparatus; a man, too, whose prime interest is in the mechanism of his flying machine, and who, moreover, is harassed in all kinds of ways in the air—from aircraft fire, enemy machines, etc. Nevertheless, the idea of using flexible film was conceived quite early in the war. In June, 1915, the late Major C. D. M. Campbell asked me to design an automatic camera especially for use in Mesopotamia. As this camera was for map-making purposes over large tracts of unknown country it was considered necessary to handle 250 exposures at one loading, each photograph to measure 5 ins. x 4 ins. There is no need to point out the great

obstacle in the way of designing an instrument to fulfil these requirements if one had to deal with the weight and bulk of 250 5 x 4 plates. Therefore, I naturally turned to the use of film, and, profiting by cinematograph experience, designed an intermittent travelling motion of the film by means of a patent claw punch movement. There have been many inventions of devices for driving cinematograph mechanism other than by hand—for example, clockwork, and electric and compressed air motors. But for a camera to be used on an aeroplane travelling always at a high speed the power was ready to hand in the wind pressure due to the movement of the machine.

The Type F Film Camera.

All I had to do—and it seemed a very simple and obvious thing—was to provide a miniature propeller or air-screw on the front of the camera. "Propeller" is, of course, a misnomer, because it does not in this case propel, but is propelled by the wind stream upon it. However, a little air-screw of this kind, measuring only 6 ins. in diameter, was found to provide ample power for the movement of the film intermittently (at any required degree of intermittency) and to operate the shutter. This camera was quickly made, and during the latter part of 1915 proved its efficiency in the Farnborough tests, and was issued for use (as the F) in 1916.

Only a small number—about three dozen—of these cameras were made (their use being restricted to Egypt and the Middle East), but a few particulars might be of interest. Ordinary sensitized film was used in 4-inch widths, coated with negative cinematograph emulsion and wound on spools having black paper ends for daylight loading. This was passed over a focal-plane shutter with separate capping device, and fed forward by the punch and claw movement referred to above, afterwards being rewound automatically on an empty spool actuated by a train of gearing. The travel of the film was intermittent, and after 5 ins. of film had passed over the shutter this was released by a cam action and the film commenced to move again. The speed with which each successive length of film was positioned over the shutter was controlled by a centrifugal "cut-out" governor driven by an air vane attached to the front of the camera. A small lever on top of the camera regulated the position at which the governor "cut-out," and thus enabled anything from one to five pictures to be taken in one minute.

In those days of trials, when queues were formed to wait for instruction or test flights, it was exceedingly difficult to obtain any reliable data, since the patient photographic officer had to put up with a different machine every time he had a test to make on an experimental flight. And some of the early flights were more amusing than instructive. I remember that a Vickers "gun bus" (a pusher type with rotary engine which had seen some service) was first pressed into use for these tests. But the vibration in the overhanging nacelle was so great that the camera had to be bolted to the floor

boards to keep it there. In the air it was only possible to make notes by a dot and dash method, so that the effect on the film can well be imagined.

When the first batch of these cameras was made a certain high official, who rather prided himself on the evolution of the cameras, gave instructions for a strip photograph to be made of a certain stretch of the Thames in order to show that the camera would produce a series of exposures without gaps and without undue overlap in the parts of the country recorded. When the film was developed a most mysterious blurring of three or four pictures was found, as well as one or two negatives which were entirely blank. After a lot of learned theorising upon the cause of this defect, it was eventually traced to its source by the admission, on the part of the somewhat irresponsible pilot, that he had looped on the way, just to see how it looked on paper? This is only one illustration of the many little difficulties with which the civilian experimenter had to contend.

Now, as I have said, the Air Force authorities were absolutely immovable in the use of plates, and in fact, about this time, in the use of the 5 x 4 size of plate. No doubt, owing to the greater number of makers of plates, compared with those of film, they were right in this policy. But plates offering more difficulties in the way of changing, it was necessary to provide a means by which the transference of the exposed plate from the upper to the lower magazine of the C type camera could be done with greater certainty than by human operations. A defect of the system was that unless the actuating lever was pushed over as far as it would go the plate (in its sheath) was liable to jam and to put the apparatus out of gear until

Type "L."

it could be put in order again on the return of the pilot. It is due to Major F. C. V. Laws that a camera was designed (the L type) in which the changing of the plates is operated definitely by power.

This camera could be mounted in any desired position in the aeroplane, usually in the fusilage directly behind the observer, and the exposure made by operating a Bowden wire connected to the shutter release. This operation simultaneously engages a train of gearing actuating a sliding rack, which moves the exposed plate into a receiving light-tight box. At the same time the gearing also re-winds the shutter and sets it for the next exposure. The power for these operations is

derived from a small wind vane mounted on the side of the aeroplane and connected to the camera by an exposed flexible shaft similar to that used for speedometer drives. It will thus be seen that the airman simply has to pull the lever making the exposure and the camera is then operated automatically by power without further attention. Another great advantage of this type of camera is that it facilitates the use of flexible cradles or vibration dampers for supporting the camera, whereas for hand operation it is necessary to employ some kind of rigid attachment, and this within reach of the airman. Major Laws patented this camera early in 1917, and under his instructions I worked out its manufacture, employing as the power for the changing operation the air-screw used for the film camera. This L type of camera, taking 5 x 4 plates, has perhaps been the one most largely employed by the Air Force. It is made so that it can on occasion be operated also by hand.

Both these principles were adopted in the later model, the LB, which I designed, and which was made by my firm as well as by others. The main object in designing the new model was that, owing to the greatly improved anti-aircraft defences and marksmanship of the enemy, it became necessary to fly at much greater heights in order to attain any degree of safety, and this meant employing longer focus lenses up to 20 ins. Further, photography was now being used for contact patrol work, which meant rapid flights at low altitudes over the enemy trenches and the use of 4 and 6 in. focus lens. The construction of the old L type would not permit of this wide variation in the angle of the light rays, and it was found necessary to employ a self-capping type of shutter. A notable step in advance which was embodied in the LB was the method of fitting this shutter. This was interchangeable, and was so constructed that it could be removed without disturbing other parts of the mechanism. The shutter is a part of the apparatus most susceptible to derangement, and the advantage of replacement in this way was obviously a very considerable one. Other essential features in which this camera scored over

The Type "LB" Plate Camera.

previous models were that all attachments, such as power drive, Bowden release, etc., were made to fasten with spring clips without the use of tools; a great point in considering the ex-

tremely awkward and "un-get-at-able" positions to which the camera was often relegated.

Strangely enough, the last new model which I had accepted by the Air Force was an automatic film camera; very similar in action though widely different in design to my first attempt at aerial cameras in 1915. Though very successful in its initial tests, this L.F., as it was called, was not completed in time to prove its worth in the field—or, rather, over it—but shows that latterly there was a tendency to use film instead of plates for aerial work. So far as peace requirements, survey work, and other industrial uses are concerned, I have not much doubt but what film will be in greater demand than plates, both from the point of ease of manipulation and lightness. In this latter respect the L.F. had the great advantage over its predecessors that, though weighing only one-half the LB, the photograph was four times the size, 18 cm. x 24 cm., and the capacity forty exposures at one loading, instead of eighteen. The action of the camera is very similar to the L type, with

The "LB" Type as Mounted on the Aeroplane.

the addition of an intermittently pressure pad to keep the film flat and rigid at the moment of exposure.

For map-making, topographical work, and survey generally, the action of the camera may be made continuous by a simple alteration to the gearing, but in my opinion a narrower film would be more convenient to handle, and could cover the same ground by doubling the number of photographs taken. Say the exposure aperture was 4ins. wide by 10ins. long, the film, travelling at right angles to the direction of flight, would then cover the same track of country as the wider film, with the additional advantage that less covering power is required of the lens. The question of the camera support or fixing in the aeroplane is largely a matter for individual selection to suit the type of machine to be used and the purpose for which the results are required. The swinging cradle, or gimbal suspension, which has been advocated undoubtedly ensures a certain economy of film or plates if correctly adjusted, for providing always a vertical optical axis, and thus reducing the necessity for overlapping. It is doubtful, however, whether the additional apparatus is of great utility, particularly in the modern aeroplane, and also in view of the fact that remarkably good maps have been made with a stable attachment, and that under difficult conditions in the war area.

COLIN M. WILLIAMSON.

HEAD OVER.—Owing to the fact that this issue has had to go to press three days in advance of the usual time a number of notes, letters to the Editor, and the report of the lecture by Major F. C. V.

Laws, of the Royal Air Force, on aerial photography at the Royal Photographic Society on Tuesday evening last has had to be held over until next week's issue.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
 The Camera and the Lens (Jan. 10).
 Managing the Sitter (Jan. 17).
 Backgrounds (Jan. 24).
 Studio Exposures (Jan. 31).
 Artificial Lighting (Feb. 7).
 Printing Processes for Portraiture (Feb. 14).
 Studio Accessories and Furniture (Feb. 21).
 The Surroundings of the Studio (Feb. 28).
 Studio Heating and Ventilation (March 7).
 The Postcard Studio (March 14).

The Printing-Room (March 21).
 About the Reception Room (March 28).
 Home Portraiture (April 4).
 Portable Studios (April 11).
 Copying (April 18).
 Handling the Studio Camera (April 25).
 More About Lenses (May 2).
 Enlargements (May 9).
 Advertising the Studio (May 16).
 Mounts and Mounting (May 23).
 Business Methods (May 30).

PHOTOGRAPHING CHILDREN.

MUCH that has been written about child photography is now hopelessly out of date, for the modern juvenile is a very different article from the carefully repressed Victorian youngster. We have only to look at Millais' "First Sermon" to see what the "good" child of bygone days was like and Hunt's "Naughty Boy" to find a good specimen of the bad one. In those days Mr. Robert Faulkner was celebrated for his beautiful child pictures produced on collodion plates, and they would certainly stand comparison with the best of the present-day work. But, fine as they were, they lacked the vivacity of the modern child; there was a general appearance of good behaviour about them, and even when there was a smiling face it was perfectly decorous.

The most important qualification for becoming a successful portraitist of children is a natural love of them, and the next is a thorough knowledge of their little ways. For this reason we now find that a great proportion of the best child pictures are made by women. Nevertheless, I have not found that to belong to the sterner (?) sex is a great disadvantage so long as the photographer is himself willing "to become as a little child" and be one with his tiny sitters. There must be no appearance of hurry about the proceedings, for a few minutes spent in making friends will save many minutes in taking the portraits: an effusive or gushing method of greeting the child often serves only to scare it; in fact, it is often useful to ignore its presence at first, and to let it become accustomed to the studio before addressing it.

The manipulation of the camera should be as unobtrusive as possible; if a capable assistant can take charge of this department, preferably without speaking, so much the better. As, however, studio work is usually a solo job nowadays, as little fuss as is possible should be made. In my experience I have found it to be a good plan to focus upon a fixed point, to have the slide drawn, and to entice the child into the desired place, making the exposure when pose and expression are satisfactory. Many of the old school of operators will perhaps regard this as too risky, but anyone who is used to hand-camera work knows what can be done by judging distance alone without relying upon the focussing screen at all. For this reason I prefer to use a short focus lens—a 10-in. at the most, and very often an 8½-in., with an aperture not smaller than $f/4$. Even with this opening there is a certain amount of depth and a movement of two or three inches backward or forward will not throw the image hopelessly out of focus. Quite recently I photographed an exceedingly restless youngster, who insisted upon talking to me without intermission, swinging himself to and fro as he sat. I chanced the exposure at the end of the swings, and got perfectly sharp results on a sitting pose,

while standing ones were obtained by placing some toys on a stool, focussing upon them, and "catching" him when he came to inspect them. All the time he was quite unconscious that anything but amusement was going on, yet the result was four good negatives out of six exposures, which is not bad with a difficult sitter who had baffled two other photographers. This clearly proves that it is quite a mistake to try to treat children as if they were grown up sitters—that is to say, to attempt to pose them in the ordinary way and to trust to their keeping their position till the exposure can be made; "good" children will do this, but, as a rule, the effort to keep quiet is evident in the photograph, and the vivacity, which is the chief charm in a child portrait, is altogether lacking.

Children, it should be noted, do not require the same kind of lighting as adult sitters; they have no lines or wrinkles; their complexions, and in most cases their hair, is light, and a much stronger illumination is possible than with adult sitters. I once had a studio with French windows opening on to a garden, and have made many good portraits with the little model standing just inside the opening; even when the direct sunlight only just missed the figure there was nothing wrong with the modelling. There was the additional advantage that the youngsters could run out on the lawn and sometimes gather a flower or two between the exposures, making the work pleasant for both operator and sitter.

On one point I have long been firm, and that is in only allowing one person to remain in the studio with the child. In my early days I have suffered from mamma, grandma, and nurse all fussing round at once, arranging and re-arranging the clothing, and when one attempted to snatch an exposure simultaneously trying to draw the child's attention. Now I know better, and if it is a choice between mother and nurse, I always endeavour to retain the nurse. I need hardly say that this has to be done with great tact, or serious offence may be given, but I am pleased to be able to say that although I have never kissed the Blarney Stone I have never had any serious difficulty. Whoever stays with the child must keep close to the photographer, so that the child will not be tempted to turn its head from the operator to the third person, and the latter must be cautioned not to speak to the child.

Various devices may be used to attract attention, but care must be taken to avoid an appearance of strained expectancy: a momentary glimpse of a toy will often produce a pleased expression, or with an older child a simple conjuring trick may be tried. To do this I have pressed the bulb with the foot, so that both hands may be free, and this has the additional virtue of entirely concealing any photographic intention. The "little bird" dodge so universally believed in by photographers is a bad one. It may keep a child still for one

exposure, but if there is no bird forthcoming the child will resent it and will not be deceived a second time. On the other hand, a mechanical bird which really sings is a great acquisition in the studio, and will work wonders with almost any average kiddie. Make it sing a note or two, and then tell the little one that it will sing beautifully if he is good, and he will wait happily for the fulfilment of the promise.

Older children, say of ten or twelve years of age, require quite different treatment; they quite understand what is going forward, and their very anxiety to facilitate arrangements is the chief obstacle to getting an animated expression. Even with them it is better to make all preparations as unobtrusively as possible, and, under pretence of waiting for something, to engage them in conversation on a subject that will interest them and put the photography out of their heads. In a minute or two you should be able to learn whether cricket or tennis, Peter Pan or Hawker, river trips or motoring, is a congenial subject. Although I detest the things, I have got a little girl quite enthusiastic over side-cars, and so it is with many other subjects.

I may seem to have dwelt unduly upon the question of securing the sitter's attention and producing an animated expression; but, after all, that is the main thing we have to do if we are to make good child pictures. With adult portraits expression is one of the most important factors; with children it is everything. They are not photographed for the sake of their clothes—very often there is very little to speak of in this line—but expression is everything. Even if the child assumes an awkward pose, though children seldom do, try to secure the expression if it is a good one. I lately saw a beautiful enlargement of a child's head which was a pleasure to look at, even though one had never met the original; and I was shown the negative from which it was made. In this both hands had moved and the legs were astraddle in a most ungraceful way; but the head was worthy of Raphael, and gave me more satisfaction than his chubby cherubs peeping over the frame.

Actual babies—that is to say, children not able to walk alone—are not very interesting subjects; the most that can be hoped for is to catch a smile. To succeed in this a little knowledge of the routine of baby life is necessary; in fact, I cannot understand how a man who has not brought up a family can manage to tackle babies at all. There are certain times for feeding, outdoor strings, and sleep, and if these are not regarded there is trouble. Such sittings are usually by appointment, and whoever makes this should take care to fix the sitting so as not to clash with them. If the mother has previous experience she will raise the question; but if she does not, the receptionist should do so. A hungry or sleepy baby never looks happy, and any attempt to prod or shake it into activity generally results in squalls, loud and long. In such a case it is useless to waste time, and another appointment has to be made, which could have been avoided by fixing a suitable time in the first place. Many mothers insist upon having very young children taken in a sitting position, although the baby is really not able to sit up properly, and for these I have found the baby-holders extensively used in America, although not often seen here, very useful. A home-made substitute can easily be constructed of wood, giving a comfortable and safe seat in which the mite can neither roll about nor fall forward. It is, roughly speaking, a shallow box with two sides removed and the remaining two cut down in curves, so that nothing is left at the front edge. The sharp corner in front of the bottom is cut into a half-circle and well padded with wool or flock; the sides are padded into a comfortable curve, and the whole covered with soft material. At the back a long, broad tape is fastened so that it can be secured at one end with an ordinary waistcoat buckle; or, if preferred, the two ends can be tied in a bow. The child is

seated as in a chair and the tape passed round under the arms and fastened, hiding it as much as possible in the clothing. The skirt can then be arranged and the feet shown. Note—most mothers see great beauty in a baby's toes.

Regarding posing there is little to say, and perhaps the best advice that can be given is the historic, if hackneyed, "Don't" of Punch. To quote Mr. H. P. Robinson: "The fact is there can be very little posing of a young child; you must do not what you would, but what the child will allow. There is one thing open to you—you may so arrange your furniture and accessories that the child shall ultimately take a good pose." Unfortunately, all operators do not realise this, and wear out their own, the child's, and the mother's patience in attempting to pose the child according to a set formula. I have known such, when they have come across a photograph or engraving which they have admired, to make the most strenuous endeavours to twist their next model into a similar pose. It must never be forgotten that we all have our little peculiarities of pose, and that a position which is comfortable to one person is torture to another. So it is with children. Some will drop into a natural pose which is very pleasing, while others can neither be cajoled nor forced into anything of a similar character.

Only a few words on apparatus and accessories are needed. If there is any choice, the camera should not be a large one, as a small camera is less obtrusive and easier to handle. Some successful operators advocate reflex cameras, but I cannot say that I care for them indoors. A number of dark slides should be to hand, as nothing is so annoying as having to change plates just as a child gets into a happy mood. The camera stand should allow the lens to be lowered within two feet from the ground, so as to enable a child on a low chair or footstool or playing on the floor to be taken without tilting the camera too much. The Hana and Semi-Centennial are stands of this type. If such a stand be not available, it is a good plan to fit a strong square stool with a tilting top so that the camera can be fixed upon it when needed.

For those who prefer it, the child may be raised to a convenient level by means of a platform, and this method has many advantages. In the first place, it is more comfortable for the operator, and, in the second, it keeps the child from wandering about. When artificial light is used, the sitter can be brought nearer to the lamps, with a consequent shortening of the exposure, a consideration often overlooked. The construction of the platform is a matter of individual taste. Some prefer a plain board like a drawing-board with folding legs, but I have found that one made of two boxes, placed side by side, to be most convenient, as it takes up little room and needs no fixing up. Each of these boxes may be 42 ins. long, 21 ins. wide, and 12 ins. high, covered with plain cloth. When in use a soft rug or nursery crawling blanket is thrown over them, and when out of use they can be stood on one side in a passage or corner of the studio, where they can be used as seats.

Some small articles of furniture, such as little wicker chairs and tables, are useful aids to posing, and often take a child's fancy, but I do not care for miniature reproductions of ordinary furniture. They are not found in the average home, and give the picture a made-up appearance. With regard to toys, there is much divergence of opinion. Some pin their faith to them as a means of pleasing the child, while others regard them as worse than superfluous. I think that there is something to be said on both sides. With some children toys will make them oblivious to anything else, and there are then few opportunities for getting a glimpse of the face while others handle them. Other children will show them to the operator or mother in a very pretty way. Care must be taken to avoid metal toys or wooden ones with sharp corners.

MASKED PRINTS WITH PRINTED-IN BORDER TINTS

THERE is no doubt that in many cases prints from negatives of suitable subjects masked to print with a white margin, and then a border-tint printed in, are remarkably effective, and give an air of distinction which appeals to many. Employing heavy-weight paper, no mount is necessary or desirable, but, naturally, attractiveness will be enhanced if each print is enclosed in a neat folder. As a general proposition, it may be said without fear of contradiction that seductiveness is usually expensive to somebody. As a matter of fact, it generally takes good care that it is, and the present case need not supply the proverbial exception.

Perhaps the simplest form of all combination printing consists in placing a border-tint around the picture, and yet comparatively few printers seem to have clear notions on the subject. A method of registering on the film "Cosway" borders

Fig. 1.

was described by the writer in last year's "B.J." The procedure for registering border-tints is on the same lines but far simpler, and a novice, carefully following step by step the following instructions, should experience no difficulty. If the printer be possessed of ingenuity, once the simple principle of the registration is grasped, more elaborate effects can be planned, or the method can be applied in other directions. Some photographers make it a practice of supplying portraits with two or more printed-in tints, often supplemented by narrow lines, all, usually, somewhat faintly printed. These are but an extension of the same idea, but the exact *modus operandi* is not always easy to discover, as tricky dodges may, and in some cases do, form part of the scheme.

No novelty is claimed for the method to be described, though the procedure may have some points of novelty, nor is it suggested that it is the only way; but it is a simple way, one that works well, and takes but little time to put in operation. Platinotype has been employed by the writer, but carbon and the bromide process are equally applicable, the latter with small modifications, which may suggest themselves to suit particular apparatus. No excuse is offered for describing all the steps very fully, as following them in any case is apt to be wearying, which is accentuated by undue compression, even if it does not lead to ambiguity. For the sake of completeness, Fig. 5 is included, showing a border-tint printed around a portrait.

The Masks.

In Fig. 1 the outer dotted lines A represent a double thickness of black needle-paper folded bookwise at *e*, in its folded state a little larger than the size of the printing paper to be employed. Approximately in correct position relative to the margins, describe the rectangle *f* to the picture size required. To prevent subsequent reversal, mark the top T and also the uppermost faces of both leaves, or flaps. Unfold paper, cut *f* out, and preserve the piece cut out. Refold, and with a finely pointed pencil reproduce the rectangle on the underlying leaf (shown in dotted lines on B, Fig. 2), using the edges of *f* for the purpose. Slip a piece of white paper between the leaves, and setting off points from the edges of *f*, describe in correct position the rectangle *g* the size of the printing paper. For a 5 x 4 upright picture masked on 10 x 8 paper, the margins at the sides will therefore be two inches. Many prefer

Fig. 2.

the top margin to be of the same width, but this is a matter of taste, and also dependent upon the length of the paper relative to its width, and the proportions of the picture.

It is essential that the left and top lines be drawn in correct position and parallel to the opposite edges of *f*; the lines on the right and at the bottom do not require exactitude; indeed, they can conveniently be set a little further away than the width of the margin determined upon. With the paper folded the rectangle *g* is cut out of both leaves dead on the line on the left and at the top. The line on the left, nearest the fold, *must be cut last*, an obvious necessity, but occasionally forgotten.

We have now secured two masks which, placed against registering marks, or stops, will interchange in exactly the same position. What was the underneath leaf B (Fig. 2) is taken, and setting off points from the rectangle drawn through *f*, a larger rectangle *h* is described, the outside size of the border-tint decided upon, and it is then cut out. Slightly rounded corners are liked by some. The piece cut out of *f* has 1-16 in., or a shade more, trimmed off the top and one side, reducing its superficial measurement by 1-32 in. all round.

Registration.

We have now to register the picture with the border-tint, and protect the former from light-action whilst the latter is being printed. The method first to be described gives soft

outlines to the outer boundaries of the tint, with its inner boundaries vignetted into the picture, a method which does not call for very exact registration; it results in a soft line of demarcation, darker in tone between picture and tint, which in most cases is effective rather than otherwise.

The outer lines of D (Fig. 4) represent a piece of sheet glass

Fig. 3.

the next standard size larger than the printing paper, a 12 by 10 sheet for 10 by 8 paper, for instance. The picture-mask *g* is temporarily placed on the glass and held by gummed strips of paper, or by a weight. (In the diagram the border-tint mask *h* is shown in its final resting-place, but the position is the same.) Three pieces of thick cardboard (see post), about half an inch square, are coated with adhesive, and pressed up

Fig. 4.

against the mask so as to be just in contact in positions shown, which are recorded in pencil lines on the mask. The piece *f* is taken, a dab of adhesive applied to the middle, and it is inserted centrally in the opening from which it was cut and caused to adhere. No shift of the mask is permissible during these operations. The picture mask is now replaced by the border-tint mask B (Fig 2), and the latter adjusted to the three card stops, and fastened by gummed strips on the right and at

the bottom, and things are as shown at D (Fig. 4), the gummed strips not being illustrated.

Finally, the negative is fixed in a cardboard carrier indicated by the outside lines at C (fig. 3), and its mask adjusted in correct position, secured as first mentioned, and three stops, this time of thin card, are affixed exactly as before.

Printing.

The printing paper is adjusted to C (Fig. 3), and pressed against the stops, and when sufficiently printed removed. At this stage we have a print with a white border. It is then adjusted to D (Fig. 4), with a sheet of thin glass the same size as the printing paper interposed between its sensitive surface and the compound mask, which separation vignettes the border-tint into the picture and affords a soft outer edge. Accordingly, the cardboard stops must be slightly thicker than the combined thickness of the interposed glass and the printing paper, or the latter cannot be registered*.

Remarks.

When printing the border-tint a sheet of ground glass over the frame is advisable; with naked artificial illuminants opal glass may be necessary. Some opal glass has been found so wedge-shaped as to afford a tint perceptibly graduated, useful in some cases. If any fairly transparent paper of even texture be at hand it may be substituted for the glass support D (Fig. 4), and will act as its own diffuser.

Should the border tint be required with sharp outer edges,

Fig. 5.

the procedure is the same as described, except that the intervening sheet of glass is dispensed with, and the cut-out piece *f* is placed on the other side of the glass D (Fig. 4), away from the mask. In this case it is stuck down first and the mask adjusted to it, not vice versa. When employing paper as a straight edge for pencilling, and also when adjusting the stops to the masks, a steel rule pressed down close to the edge will prevent the paper buckling.

* This method suggested an easy way of securing a regulated amount of diffusion in contact prints, described in the *entre l'Almanach* and in last year's "B. J.," May 3, 1918, p. 205. The effects obtained are often very pleasing.

Alternatives.

The foregoing methods present one disadvantage, inasmuch as the cardboard carrier and mask cannot be used as they are for other negatives, unless the subject happens to compose correctly when a fresh negative is inserted in the card carrier, which is hardly likely to be the case, necessitating removal of the stops and replacing by others in other positions.

This may be corrected by making a third mask about one inch larger each way than A (Fig. 1), with its aperture (corresponding to *f*) enlarged roughly in the same proportion. Similarly, the cardboard carrier holding the negative will have to be larger than the third mask. The only difference in procedure is that instead of adjusting the picture mask A (Fig. 1) to the negative, it is laid down centrally on, and fastened to, the third larger mask, and the stops are affixed

to the latter. This double mask, two-thickened only towards the margins, can be adjusted over any negative whose subject is appropriate to the "picture opening," when printing is conducted precisely as before. In addition to the full-sized rubber pad used in carbon and platinotype printing, one rather smaller than the opening in the third mask is placed at the back of the tissue, or printing paper, so as to escape the two thicknesses of the mask, which ensures central pressure and sharp prints.

It will be obvious, when mentioned, that mask B (Fig. 2) need not necessarily be opaque, but transparent in part or in its entirety, a suggestion which opens out possibilities of double tints and other more ornate effects. In such a case, before starting work, it is stuck to A along its left-hand edge.

E. A. S.

GLAZING TROUBLES AND REMEDIES.

SINCE the start of the great war there seems to have been a recrudescence of troubles in the glazing of prints, more especially postcards. That a lot of the trouble has been caused by the "substitute" chemicals goes without saying, and the short supply of "baryta" has also had a lot to do with it. Apart from these two primary causes, there are several others, most of which, since they are due to faults in the methods of working, are more easily remediable. In the first place, take the case of prints sticking to the glass or other temporary support. This should never occur to the even moderately skilled worker, and should it do so the immediate cause should not be hard to discover. The most probable cause is a dirty or improperly prepared glass, especially when used for the first time. The best method of procedure with new glass is to clean thoroughly with weak ammonia or water, or, preferably, petrol, then to wash away all trace of this, dry the glass with clean linen rag, and then give a coating of ox gall and water (half and half), or even pure undiluted ox gall. Beginners are apt to think that when ox gall is mentioned it refers to the "prepared ox gall" sold by artists' colormen, but for the purposes of glazing prints the ox gall should be obtained from the butcher, who will usually let you have a good supply for a few pence. This, which we will call stock, should be kept in a stoppered bottle, and a few drops of formaline may be added to improve its keeping qualities, more especially in hot weather, or if stored in a warm place. For general use a dessertspoonful of the stock gall should be added to a quart of water, which will be found to make a good working strength. If stronger than this the tendency of the prints will be to drop off the glass when only barely dry, and the high gloss will consequently deteriorate. The best glaze is obtained when the prints do not drop off at all, but require just one corner raising and stripping, just as they did in the old days, when we collodionised the glass. Another advantage of stripping versus dropping off is that the prints are flat instead of being curled inwards, and if put under a weight—say, a few boxes of negatives—will remain flat until the order is ready to make up and despatch.

When preparing the plate for the reception of the prints, do not pour ox gall on, but simply take a clean linen rag charged with ox gall—i.e., soaked in the solution and then squeezed out—and wipe the glass with the same; wipe lightly and all over, not forgetting the extreme edges. Then take the prints out of the water and lay carefully on the glass, cover the whole with a sheet of waterproof rubber sheeting—it is immaterial whether the rubber side or the cloth is downward—and squeegee lightly but firmly from left to right to remove

any air bells. The form of squeegee differs with different workers. I once knew a man who could obtain good results with a roller squeegee, but where the one succeeded dozens would fail. My personal choice is one made of soft pine, about 15 ins. long and 3 deep, of course with rounded edges. This gives a more certain pressure than the commercial rubber squeegee, besides being much cheaper and less likely to get out of order at the most inopportune moment. Now turn the glass over and examine carefully to see if any trace of air-bubbles remain, and proceed with the other side and stand up on edge to dry. Never place near a fire, or in the sun, until the cards are quite surface dry. If these directions are followed there will be no sticking.

The next trouble that arises is the constantly recurring crop of dull markings, sometimes large, sometimes small, and at others practically covering the whole of the print with wee dots, or, as our North Country folks term them, "blebs." For these the assistant who wields the squeegee usually gets the blame, and not always rightly. An occasional air-bubble will often occur, but that can be usually distinguished from other dull markings by its size and shape. It is these other markings that usually puzzle the worker, and I have personally given much time and thought to trace them to their lair, and then exterminate them. The main cause lies where so many faults have lain before, in the bad washing of the prints after fixation. By bad washing it must not be understood that I mean insufficient washing, for in the production of blebs excess is just as frequently to blame as insufficiency. Should the fixed prints be thrown into a bath or tank and allowed to lie on each other anyhow for ten or fifteen minutes, and then be removed and transferred to the glass, the result will be "blebs." Should the prints be left washing and constantly moving for two or three hours and then squeegeed, the result will be "blebs." The worker, having tried both ways and having obtained a successful crop in each case, at once blames the emulsion maker or coater, but let him try again. Wash the prints in four or five changes of water, turning them by hand the whole time for five to ten minutes, and then squeegee at once without further soaking, and, lo and behold! the "blebs" have gone; the free hypo has been washed out, and the gelatine emulsion has not had time to become decorated, and so the prints are perfect, at least so far as the glaze is concerned. To prove the correctness of this hypothesis, the reader who is at all sceptical may try the following experiment:—Take a print fresh from the fixing bath and squeegee it. Let another print be thoroughly and carefully washed, and then leave it soaking in water for two days, then squeegee

that and note the results. They will be similar, almost identical, one absolute mass of dull spots.

Air-bubbles arise from one of two causes, either bad squeegeeing—i.e., either insufficient pressure being brought to bear on the prints, or passing the squeegee over the print in more than one direction, and so pressing back air already expelled by the first pass of the squeegee. The latter is a very general cause, but perhaps not so much so as the practice of taking a batch of prints out of the water at once and placing them in position on the glass with an uneven amount of wetness on the surface. The portions where the water has run off at once adhere to the glass and imprison air between them, and the action of the squeegee then churns this air into several small bubbles, or sometimes prevents optical contact over a fairly large space. Prints should be taken from the water singly and placed at once direct in the position they are to occupy on the glass sheet. Movement, either by lifting and replacing or by sliding along the glass, is apt to cause bubbles, and be it noted that the prints should not be placed in actual contact with each other. Better have one or two less on the sheet than, by cramming it to excess, obtain slight overlaps, which not only spoil the effect of the glaze, but cause uneven drying.

As to the actual drying, it should not be too rapid nor too prolonged. Should the prints, while actually wet, be placed near a fire or heating apparatus, or in the sun, the moist heat will cause partial melting of the film and result either in a bad case of sticking or the edges will curl away from the glass, and either the prints will fall off while still damp or they will dry with a patch of glazed surface in the centre and almost matt around. In the latter case they are irretrievably spoiled, as even if again soaked they will never glaze properly. A warm room, or preferably out of doors in fine weather, is the best drying ground for glazed prints, only if there should be a wind it will be necessary occasionally to watch that the glasses are not blown over or the prints blown away.

If the emulsion surface of the paper or postcard is of the dull, semi-matt appearance that has been so often the case of late (baryta again), it may be an advantage, in cold weather, to warm the final washing water slightly, and to omit altogether the alum bath. Of course, the water must not be made sufficiently warm to cause stickiness of the emulsion, only just sufficiently so as to slightly soften, not melt, the surface of the prints.

C. BRANGWIN BARNES.

FILTERS FOR PANCHROMATIC PLATES.

THE advances which have been made recently in colour-sensitive plates render it desirable that the users of these should give some attention to the making and selecting of filters. In the early days of orthochromatics, and, indeed, for many years after, the general practice was to be satisfied with any piece of yellow glass or gelatine. Later on, well made filters of stained gelatine cemented between flat glass were on sale. Some of the plate-makers showed commendable enterprise in this direction, although the degree of correction aimed at was seldom much more than sufficient for spring flowers or early summer foliage. Indeed, as colour sensitiveness then stood, full correction for autumn landscape, summer or autumn flowers with their wide range of colour contrasts, and for paintings could only be obtained by the use of a filter requiring some forty times the ordinary exposure. Such prolonged exposures made it difficult to deal with anything but still life and similar subjects, and, even so, the gaps in the colour-sensitiveness made the correction somewhat patchy; orange yellows and some shades of green being rendered much too dark.

The advent of the Autochrome and other mosaic colour plates had the effect of directing popular attention to orthochromatics in general, and several brands of panchromatic plates were produced. Notwithstanding their generic title these plates, although showing great improvement, were not equally sensitive to all colours, and fairly deep filters (say ten times) were still necessary to secure reasonably good correction.

The war, which interfered sadly with photographic activities, had at least the effect of calling attention to British slackness in the matter of dyes in general photographic sensitizers in particular, and successful efforts have been made to recapture and extend this branch of trade and to introduce new and valuable sensitising agents. The plate-makers have not been slow in availing to themselves of these new materials, with the result that plates are now obtainable which, although not equally sensitive to all colours, are much more nearly so than their predecessors, and, at the same time, are so rapid that even with a fairly deep filter in use it is possible to give an instantaneous exposure upon a well lit scene and still have a thoroughly exposed negative.

Some of the older filters will give reasonably good results with the new plates and that without prolonging the exposure unduly. A 40-times filter for example may not prolong the exposure more than four or five times, and what is known as a K3 filter will add perhaps a fourth to the exposure.

If, however, the best results are to be got it is necessary that the filter should be adjusted to the plate, and it is desirable that the earnest photographer should be able to do this for himself. The plate maker may issue filters which are correct for some purposes, but they are likely to fall short when employed in another type of work. For example, with one brand of panchromatic plate spring and early summer flowers and foliage are rendered almost perfectly without a filter, some blues, the blue of the cornflower, being rendered a trifle too light and greyish green just a little too dark. A light

emerald yellow filter which lengthens the exposure by perhaps a fourth or less will hold back the blue till the green is sufficiently exposed. For the deeper tinted foliage of summer a stronger yellow would be necessary entailing an exposure of about one and a half times; a group of strongly contrasted autumn flowers would require a deeper yellow without a trace of green, and an oil painting for which a full palette has been used would require a very deep yellow, doubling the exposure. Obviously it would be absurd to handicap the speed of the plate by using the last mentioned filter in photographing with a hand camera a scene in which full reds did not appear.

It may be said that the prejudice against colour sensitive plates, which existed so long, had its origin in the too prevalent practice of using a strong r filter than was needed, and at the same time attempting to cut short the exposure. Over-correction is due not to the plate but to short exposure coupled perhaps with prolonged development. When there is any doubt about being able to give a sufficiently long exposure it is better by far to substitute a lighter screen and risk under-correction.

The photographer who desires to make his own filters should know something about the materials he has to employ. Optically worked glass flats are sometimes recommended, if truly flat, the price is prohibitive. Patent plate glass of good quality will make reliable filters. The thickness should be in

proportion to the area—for filters 1 inch in diameter, two pieces 1/16 inch thick; for those 2 inches in diameter, 1/8th thick; and for larger sizes, 3/16 or more. The glass must be flat on both surfaces, and as nearly parallel in thickness as possible. If a piece of glass is held at such an angle that the bars of a window are reflected from it, it will be seen that there are two reflections, one from the upper and the other from the under side. If a straight line is reflected as straight, and the two reflections are, and continue to be, parallel as the glass is revolved on an axis at right angles to its surface, the surfaces are reasonably flat. The reflections will probably approach to or recede from each other even if the glass is kept truly in the same plane during examination, and show that the glass is not truly parallel in thickness—that it is, in fact, wedge-shaped. Perfection in this particular cannot be hoped for, but if the thin edge of one piece is laid over the thick edge of the other, no displacement of the image will take place.

Picric acid, ammonium picrate, tartrazine, naphthol yellow, brilliant yellow, filter yellow K and fast green are all useful stains. Some of these came from Germany, and now may not be obtainable; but a new English dye, filter yellow A, has been brought out, and is quite good; with that and the picrates and a bright bluish green, little difficulty should be met with in making up a filter to match any plate. The picrates cut out the blue very sharply, and used alone are quite good when cloud negatives are wanted, but do not work so well when a long range of colours has to be dealt with.

Those who have to make large numbers of filters to standard tints find that the best plan is to add an exact proportion of dye to a measured quantity of gelatine solution and coat the sheet of glass cleaned, vaselined, and levelled, with a certain number of minims to each square inch of surface. Mr. A. J. Bull, lecturing at the Royal Photographic Society, stated that 1 milligramme of filter yellow A to each square inch gave a fairly correct rendering of coloured objects with modern panchromatic plates.

The method has the advantage of standardisation, but presents many difficulties in operation. A fairly large quantity of solution must be made up, as it is desirable to coat several sheets of glass at one time, drying is difficult; worm-markings sometimes appear, and, when every care has been taken, the gelatine will not always strip from the glass. The writer has for years employed a different method: he purchases at a small cost sheets of clear unstained gelatine, as used in bon-bon making and by engravers and others in making tracings of drawings. This gelatine has been treated with formaline or other hardening agents, so is easily handled when wet. It can be bought from J. Bousquet, 28, Barbican, London, E.C., or from L. Cornelissen and Son, 22, Great Queen Street, London, W.C.

The gelatine should be cut into squares a little larger than the finished size of the filter, and some pieces of plain glass (for a temporary purpose to be explained presently) and cardboard should be provided. A little of the selected dye is to be dissolved in distilled water; the strength may be such that a depth of half an inch in a white dish appears somewhat deeper in tint than the filter is to be. A piece of the gelatine is immersed in the solution and allowed to soak till it has taken up sufficient of the colour. If the solution is too strong, the gelatine will absorb it irregularly; it is better to err on the weak side, so that the gelatine becomes quite limp before it is sufficiently stained. It will absorb nearly the whole of the dye if allowed to remain in the solution long enough.

Some arrangement for keeping the gelatine flat while drying is necessary; if pinned up by the corners it will cockle and twist so that when dry it cannot be brought flat again. It

must be stretched as a sheet of paper is when a water-colour drawing is to be made. The gelatine cannot be stretched on a board as the two would adhere together, but if a piece of glass (not necessarily plate glass) is laid in the centre of the board the gelatine will adhere at the edges only.

The gelatine will expand considerably, and when stained deeply enough a piece of the cleaned glass mentioned in the previous paragraph is slipped under it and the two lifted out together. The gelatine, being larger, will hang down on all sides. The edges should be lifted up and the glass with the gelatine on top laid on a piece of cardboard, the edges of the gelatine being then stroked down into close contact with the card. The cardboard will quickly absorb the water from the parts of the gelatine in contact with it, and as it dries adhesion will take place. The part of the gelatine which is over the glass will dry more slowly, will contract in drying and become quite flat. When hard, a knife cut round the edges of the support will release the gelatine, which will have no tendency to adhere to the glass.

It is desirable to stain a dozen or more pieces of gelatine with each tint of colour, but in different degrees of shade from a very light tint to the deepest shade likely to be wanted. It is not as a rule wise to mix different dyes, because some mixtures will throw down a precipitate and also because some dyes are so much more readily absorbed by the gelatine than others that no dependence can be placed on the combination. When combination of tints is wanted it is better to use two or more pieces of gelatine in making up the filter.

Before cementing up it is well to make photographic tests, and for that purpose a colour chart is required. Two have been suggested by Sir W. Abney. To make these some dry powder colours are wanted—French ultramarine, chrome yellow, emerald green, and vermillion, also lamp black and Chinese white. These are to be used in the form of distemper, and ordinary photographic mountant is a handier medium than size. Some squares of paper should be coated with the four different colours so thickly that the white paper does not show through. One-inch squares of each colour should be pasted down end to end along the top of a piece of stout card. Some of the white with enough black to make a medium grey is to be painted over a strip of paper and pasted below the row of colours. Now comes the difficult part—it is necessary to darken with black or lighten with white a set of coloured squares to match in luminosity the strip of grey, and quite a number of tests will have to be made in doing so. Blue and red will each require the addition of a little white, the yellow will require the addition of black, and the green may be just correct, or it may have to be darkened or lightened according to the shade of the grey strip. The object is to grade a set of the blue, green, yellow and red squares to match absolutely in brightness the grey strip. When this is done probably no one else will agree that it is correct, but that is of little importance, as no two of the critics will agree as to the correction which should be made. It is important that the grading should satisfy the experimenter, for if that is done all photographs taken with the filter which renders the chart correctly will be satisfactory to him.

When the chart is graded a filter must be made up which will render the grey strip and the row of broken colours below it as a uniform grey tint. This is much more easily done by interchanging the pieces of stained gelatine of different colour and different depths of colour than by mixing dyes in liquid gelatine. The top row of unbroken colours will of course appear in the photograph in different shades of darkness and is useful in showing how such colours will photograph.

The alternative chart is made by coating sheets of paper with the unbroken colours, one each of blue, green, yellow and red are wanted, also one piece of black and two pieces of white paper. A toy electric motor is wanted, and if that or some-

similar is obtainable the making of the chart is a much simpler matter than the one previously described. A disc, say 12 inches in diameter, is cut out of the blue paper and either the same size of white paper. If the paper is thin will have to be mounted on thin card. A radial cut is made each from the periphery down to the centre, and it will be possible to interlace these discs together so that any proportion of white can be added to the blue. The motor must have a little run near the end of the mandrel and a nut outside that. A hole is bored in the centre of the combined disc and it is faced against the drum. The green disc should be 3½ inches in diameter, and being the middle colour requires neither black or white paper to go with it. The yellow disc is to be three inches in diameter and requires a black disc. The red is to be two and a half inches in diameter and wants a white disc. When the four discs are mounted the nut is lightly screwed up and the machine set running. By adding to or reducing the proportion of white the blue can be made to match the green disc, and the same will have to be done with the yellow and the red. If the peripheries of the coloured and the black and the white discs are divided into degrees and numbered it will be easy at any future time to reproduce the same arrangement. When all is in order the machine is set running and a suitable filter is made up as in the previous case.

The selected pieces of gelatine should be cemented between two pieces of patent plate glass, round or square as may be most convenient. Canada balsam is used, thinned out if necessary with

xylol or benzole, a small pool is poured on one piece of glass, the gelatine is laid gently on top, care being taken to exclude air bells, the other pieces of gelatine and the second glass laid down in the same way. No great pressure should be used in clamping the filter together or it may become distorted while drying. An ounce weight laid on top will be sufficient. Drying should take place slowly at about 70 or 80 degrees F. To prevent the parts slipping and to avoid having to wrench the filter from whatever it is laid upon while drying a piece of paper may be laid over a bit of flat wood the filter laid on that and pins driven round the edge.

In conclusion it may be pointed out that, although the photographs made with such a filter may be scientifically correct, or nearly so, the result may not be pleasing from a pictorial point of view. Let us assume that such a colour chart as first described forms a part of the scene to be photographed; it would be rendered as a flat grey surface with no indication that it was built up of colour contrasts. That is an extreme case not likely to occur in practice, yet in nature we may frequently find objects so uniform in luminosity, particularly in a light summer haze, that a correct colour-rendering would be unpleasantly flat. In such case it may be desirable to use the plate without a filter, or with one which allows the colour contrasts to be perceived. The experience gained in making the filters will be of great service in enabling the photographer to decide which is the best course to pursue. J. McINTOSH.

ADAPTING THE HALF-WATT TO GASLIGHT ENLARGING.

In our business it is necessary to enlarge from small negatives on to gaslight postcards and paper. The enlarger is of the vertical type, with an 8½-in. condenser, and the source of light is an ordinary 1,000 c.p. half-watt lamp. The dark room is a room built inside another room. The condenser is on a level with the dark room roof, and the light is placed outside on the roof, as shown in Fig. 1. This sketch shows the arrangement.

The image of the filament of an ordinary half-watt lamp, placed vertically over the condenser, is thrown into the enlarging lens in the form of a segment of a circle, none of which passes through the centre of the lens (see Fig. 2), and a very uneven disc of light is projected on to the easel. A side view of the filament throws a more concentrated and stronger image through the centre of the enlarging lens. (See Fig. 2)

If the lamp is burnt in a horizontal position the filament soon sags alarmingly, the lamp rapidly blackens, and it soon fails. The only alternative seemed to be to get a side view

Fig. 1.

of the filament shown in Fig. 1—i.e., by means of a mirror. This gives a very evenly illuminated disc, and also a much more luminous one. The lamp can be moved to and from the mirror—in effect to and from the condenser—by pulling one or other of the cords CC to suit different degrees of enlargement. The exposure necessary with a medium-speed gaslight emulsion is 10 to 20 seconds with thin to average negatives and with lens

aperture of $f/6$. An arc lamp might in some ways be better; but this arrangement is always ready, is operated and adjusted entirely from within the dark room, and needs little or no attention.

The negatives used vary from quarter-plate down to vest-pocket size, and are put as far as possible from the condenser. Immediately below the condenser is a box with a series of

Fig. 2.

Fig. 3.

grooves, into any of which the plate-carrier can be inserted; and in all cases the negative is put into the lowest groove which allows of it being within the cone of light thrown by the condenser into the lens. (See Fig. 1.) This permits practically the whole of the light from the half-plate condenser to pass through the negative, whatever its size, giving shorter exposures, and tending to uniformity with varying degrees of enlargement, as compared with the usual practice of putting the negative close to the condenser.

The lens used is of the Petzval type of 7-in. focus. In this connection we had an interesting experience. An $f/4.5$ Aldis 7-in. focus was substituted, the idea being to get the best possible definition, especially at the margins. It was found to be very much worse, anywhere. An $f/4.5$ Tessar 7-in. focus was then tried, also an $f/6.5$ Cooke; the former, with quite as bad and the latter with only slightly better results—in all cases at full aperture of the lenses. That three such perfect lenses should fail puzzled us greatly. The result was the same whether the negative was placed close to the condenser or not,

also when ground glass was interposed between light and condenser, and, alternatively, between condenser and negative. The idea that the lenses did not work to focus did not occur to us for some time; but eventually it was found that by moving the easel further away from the lens after focussing a quite sharp picture can be got. The adjustment necessary is such as to throw the image entirely out of focus—in fact, the result is quite "uncanny," and has to be seen to be believed. There may be some rule for the amount of adjustment necessary. In practice the writer can now gauge the distance fairly correctly by the appearance of the image. The Petzval lens works dead to

focus at $f/4$ under exactly similar conditions. Why does not the anastigmat? We have seen the effect vaguely hinted at, but not fully described or explained. It does not seem to be due to a "chemical" focus of the lens, as a red or yellow cap on the lens for focussing makes no difference. Stopping down to $f/11$ puts matters right; but if this must be done, why spend good money on anastigmats for enlarging? Our own experience is that there is no lens better than, in fact, none quite so good as, the old Petzval for enlarging from small negatives where it is necessary to use apertures larger than $f/6$.

J. C.

A METHOD OF MULTIPLE GUM-PRINTING.

ALLOWING that it is occasionally possible to obtain in a single printing a gum-bichromate picture, not only with a full range of tones, but of a freshness and spontaneity sometimes lacking in the more labourered multiple print, still the lucky combination of conditions necessary to bring about this happy result occurs so seldom, and "single" prints so repeatedly turn out intolerably harsh, that it must be admitted "single" printing is most discouraging work. In comparison with this uncertainty, multiple printing, if more toilsome, is infinitely surer of its effect, and offers a method unexcelled among pictorial processes for quality, control, permanency, and cheapness of materials.

The great bugbear of multiple printing has been the difficulty of securing accurate registration of the successive printings, and numerous devices have been put forward to overcome this trouble, but they have all proved more or less inefficient, or cumbersome and expensive. The method which I have used for years, and which enjoys the advantages of simplicity and cheapness, is to hold the negative firmly in place in the printing frame by means of a couple of set-screws; and to have the sensitised paper attached to a sheet of glass of the same size as the negative in such a way that the paper, however long it may be soaked, always returns to its original tension on drying.

Any strong paper can be used. Drawing papers like Whatman are excellent, but rather expensive. Heavy linen ledger papers, if procurable without a watermark in the centre of the sheet, are very good, but perhaps best of all are stout cartridge and detail papers, which are both strong and cheap. As a rule the hard surfaced ledger papers do not need any preliminary preparation, but other papers require to be sized.

SIZING.

Gelatine	150 grains	10 gms.
Water	7 oz.	200 c.c.s.

Soak gelatine in water for twelve to twenty-four hours, melt in water-bath, and stir in hot solution of—

Alum	150 grains	10 gms.
Water	5 oz.	150 c.c.s.

Finally add—

Alcohol	1½ oz.	35 c.c.s.
---------------	--------	-----------

The paper is pinned by the corners to a drawing board and the sizing is applied hot, and not too thickly, with a flat bristle brush. Two coats are advisable, but the first coat need not be perfectly dry before the application of the second. It is essential to know the sized side of the paper in subsequent operations, and the pin holes automatically indicate which side received the coating, the rough edges of the perforations always being on the under unsized side.

A cleaned-off negative serves very well for the sheet of glass to which the paper is to be attached, but it is better to smooth

the sharp edges with emery cloth. The sized paper is cut to a dimension two or three inches larger all around than the glass plate, and is immersed in water for half an hour or so. When thoroughly soaked, it is surface-dried between blotters, and is laid, sized side down, on a smooth surface covered with clean white paper—cheap newsprint or wrapping paper will do. The glass is then placed in the middle of the sheet, and the projecting edges of the paper are brushed over with the following:—

INSOLUBLE PASTE.

Corn starch	½ oz.	15 gms.
Water	7 oz.	200 c.c.s.
Carbolic acid	10 drops	10 drops

Mix and boil until it turns clear; then add chrome alum 2½ per cent. solution, 1 oz. (30 c.c.s.). Use cold. (This paste keeps indefinitely in a covered jar, but owing to its acid reaction should not be used for print mounting. The water that separates out in time should be poured off.)

The corners of the paper are now cut off with a sharp knife close up to the corners of the glass (Fig. 1), and the pasted

Fig. 1.

edges are folded down over the glass and rubbed into good contact. The "paper-plate" thus prepared is put away between blotters under light pressure to dry.

I prefer a gum solution that has become acid through age, and always keep in reserve a bottleful that may be anything from a month to a year old. As soon as I begin to draw on the reserve stock I prepare another supply to take its place.

GUM SOLUTION.

Gum arabic	2 ozs.	60 gms.
Water	5 oz.	150 c.c.s.
Carbolic acid	10 drops	10 drops

The gum solution is best kept in a wide-necked bottle, over

the mouth of which is stretched a piece of the thin sheet rubber known to dentists as "rubber dam," held in place by a strong rubber band.

For the bichromate solution either ammonium or potassium bichromate may be used. The ammonium salt, being the more soluble of the two, forms a quicker printing mixture with the gum, and is sometimes recommended on that account. Both salts in printing yield an impermanent image that has to be eventually "cleared"; but the ammonium salt, when used in a concentrated solution, gives rise to such an intense image of this kind that the real gum-pigment image is masked to a large extent, and without the trouble of frequent clearing it is impossible to tell when sufficient depth has been attained in the printing. This disadvantage seems to me to more than offset any possible gain in printing time, and so I always use the potassium salt.

BICHROMATE SOLUTION.

Potassium bichromate	1½ oz.	40 grams.
Water	10 oz.	300 c.c.s.

As the solution is intended to be a saturated one at normal temperatures, the exact quantity of the salt is immaterial, provided there is enough.

The sensitising mixture is conveniently compounded in a glass mortar, the pigment being put in first, the gum and bichromate solutions added, and the whole well worked up with the pestle.

The customary procedure is to coat and print for the half-tones first, then for the high-lights, and lastly for the shadows, and the proportions of gum and bichromate are varied for the different coatings. Typical mixtures suitable for thin to normal negatives may be tabulated as follows:—

	Half-tones.	High-lights.	Shadows.
Gum solution.....	5 parts	5 parts	5 parts
Bichromate solution	8-10 parts	12-13 parts	5-8 parts

For strong contrasty negatives a larger proportion of bichromate solution is indicated throughout.

While the usual order of printing is as mentioned above, it must be noted that there is nothing immutable about this, and if at any stage of the work the values appear false they may be "pulled together" with an appropriate coating.

The pigment is best measured by bulk. In the case of the moist colours the quantity can be gauged by the length of the piece squeezed out of the tube. For dealing with dry colours, the tiny chemical scoop listed by some dealers is very handy, or a small bone mustard-spoon may be utilised. The important point is to avoid too much pigment, and the beginner is always astonished at the small quantity required. As a rough indication it may be said that of dry lamp-black as much as will cover a threepenny bit to the depth of about 1-16 inch is enough per ounce of gum-bichromate solution for the high-light coating; while approximately one and a-half times and twice that quantity are about right for the half-tone and shadow coatings respectively.

But the most satisfactory way to judge of the pigment content is to spread a little of the sensitising mixture thinly on a piece of newspaper. When this is done with the high-light coating the printing should remain practically as clear as ever; the half-tone coating should slightly veil the characters, while under the shadow coating they should be decidedly obscured, but still quite legible. The golden rule is always to use too little rather than too much pigment. Too thin a coating merely means an extra printing, whereas too thick a coating, especially if deeply printed, is likely to ruin the picture.

The sensitising mixture is applied to the paper-plates in the usual way, first being spread as thinly as possible with a flat bristle brush, then softened with a wide camel-hair brush, and finally finished with a badger blender.

The printing frame, shown in Fig. 2, with the back removed, has fitted in adjacent sides two small set-screws which enter the frame just on a level with the rebate. The popular English model of printing frame in which the sides are cut away at top and bottom will need to have a piece fitted to receive the screw. The negative is placed in the frame, and the set-screws

Fig. 2.

are cautiously tightened up, but first, to avoid danger of breakage, a small square piece of rubber about as thick as the glass is interposed between the edge of the negative and the end of the screw. For this purpose I use little pieces of rubber cut from an old eraser. The sensitised paper-plate is now put in and carefully pushed up from the bottom into contact with the top of the frame, and then over from one side into contact with the opposite side. This order of adjustment must be rigorously observed in all the printings, so as to obviate failure of registration due to possible lack of squareness in the paper plate or the frame. For handling the paper-plate the rubber pneumatic plate holder (Fig. 3) used to manipulate negatives during varnishing is a practical necessity. With it the paper plate can be removed and replaced with the greatest facility, and without disturbing the negative.

Printing is, of course, controlled with a print-meter like the Wynne or Akurel, or one of the other similar models on the market. The development of the paper-plate presents nothing special, and each worker can use his favourite method. My choice is generally a stream of water from a rubber tube attached to the tap, the force of the jet being regulated by pinching the end of the tube. But on occasion I use an atomiser, a swab of cotton wool, or brushes of various sizes and degrees of stiffness.

Development being completed, the paper-plate is put to dry. When I first began practising this method of multiple printing I was much worried by the paper splitting in the course of drying, and this happened even to the strongest kinds, like heavy Whatman. Presently I saw that the annoyance was caused by setting the paper-plate on edge to dry. In this position the upper part of the paper dried out first, and, contracting strongly, pulled on the bottom part, which was still soft with moisture, so that the latter frequently gave away.

This trouble is entirely overcome by allowing the paper-plate to drain for a few minutes, first on one end and then on one side, until all the free water has dripped away, and then laying it down flat to dry. As drying now proceeds uniformly over the whole surface, splitting of the paper never occurs. If not allowed to drain long enough, however, a pool may form on the surface of the horizontal plate, causing the image to run.

Fig. 3.

If water accumulates between the glass and the paper, in order to let it escape a small piece of the extreme corners of the paper may be pinched off with the thumbnail.

When thoroughly dry, the paper-plate is coated again, and the same procedure as before is followed. It is worth while noting that the actinometer number for any given negative is approximately the same for all the coatings. The exposure required to print the more heavily pigmented shadow coating is not very different from that needed by the more transparent high-light coating, for the opacity is in the coating in the one case and in the negative in the other.

After three or four printings the picture should be "cleared" of the image formed by the bichromate solution in order to see if the permanent gum-pigment image is strong enough. A very efficient bath for this purpose is a 4 per cent. solution of sodium bisulphite, or, as an alternative, we may use:—

Alum	$\frac{1}{2}$ oz.	15 gms.
Water	26 oz.	750 c.c.s.
Acetic acid	$\frac{1}{2}$ oz.	15 gms.

Clearing is followed by washing for about 15 minutes. Before putting the picture through the clearing bath it is advisable to let it dry and expose it freely to daylight, so as to harden the image. Never cut your picture loose from the glass until it has been cleared, for the removal of the bichromate stain frequently reveals the necessity for additional printings.

Theoretically a gum-print should be completed in three printings, but this implies such a nice balance between coating, printing, and development that I suspect it does not often occur. Personally, I must confess that I have never reached a satisfactory conclusion in less than four printings, while the usual number is five or six, and some troublesome negatives have demanded as many as ten and twelve. In gum-printing it is much easier to give than to take away, and the best and safest method is to build up the picture very gradually.

Photo-Mechanical Notes.

Relief Half-Tones.

A DESCRIPTION of the way that half-tone of a text in which the letters stand out in relief is made may be of interest.

The text is printed in black ink on white paper, a half-tone negative is made with stop and exposure so that the letters are quite free from dot, while the dot from the paper ground is only a small

Proof from engraving, made as described.

one in order to keep the background dark, though if the background were required a lighter grey, the dot could be larger.

A line negative is now made of the text, and from this, a positive. This positive, having the text in black letters on a transparent ground, is stripped and superposed on the half-tone, being slid just sufficiently out of register to give the shadow effect required to show the relief. This is printed on the metal and the half-tone etched in the usual manner.—A. J. N.

Screeniness in Half-tone Engravings.

SOMETIMES the screen is very obvious in half-tone engravings, even when made with quite fine screens, and this is usually due to a want of harmony between correct screen distance and stop and exposure. If the screen is too close to the plate it may be impossible to use a stop that will give the correct ratio between it and the camera extension, which should be equal to the ratio between the screen aperture and the screen distance, in which case "screeniness" will appear; or the screen distance may be incorrect for the size of the stop chosen, or the ratios may be correct and the exposure too short, when the large dot printing in the high-lights will make the screen apparent. It is essential to have these ratios agree and the exposure correct to ensure the most perfect gradation possible in a half-tone screen negative.

However, this is perhaps common knowledge. What sometimes puzzles engravers is why of two results both made with all these conditions apparently correct, one will appear very much more screeny than the other. The explanation will be found to lie in the relation of the angle of the screen lines to the picture. This is why the experiment, many times revived, to make newspaper engravings with screen lines crossing vertically and horizontally, has never been persisted in for long, and why the four-line screen, which had vertical and horizontal lines, did not succeed.

The cross-line screen is made with lines at 45 deg. from the horizontal for the very good reason that the average human eye is much less easily able to distinguish lines at this angle than it is lines which are nearer the vertical or horizontal, the reason probably being that our eyes have had much more constant exercise in the examination of horizontal and vertical lines and therefore are more easily able to detect them. Consequently it is desirable that the copy is placed on the board so that the screen lines will cross the horizontal and vertical lines of the reproduction at 45 deg. The copy board should be marked with a vertical and horizontal line to which all copies should conform when placed on the board.

For the same reason in three- or four-colour work it is not enough to have the screen angles at the right distance apart to avoid moiré pattern, but the most conspicuous colour in the reproduction, usually the blue, sometimes the black, should be made at the 45 screen angle, and it is because this simple precaution is sometimes overlooked that one colour job looks so much more screeny than another.

Reproduction of X-Ray Negatives.

MEDICAL books and advertisements frequently require half-tone reproductions of X-ray subjects. Doctors are in the habit of examining the negative itself rather than the positive made from it, and therefore it is desirable that the reproduction should be of the negative. Unfortunately X-ray negatives are generally extremely contrasty, and therefore difficult to reproduce by putting them in a transparency holder, because before a dot is obtained in the denser parts the detail in the lighter parts is obliterated and the dot overjoined, no matter how small a stop is used. But every bit of detail is usually most important, and must be shown. Whenever the contrast in the original negative is not outside the limits of the screen process, the transparency method is the ideal way to make the screen negative. In most cases, however, it will be found necessary to make a positive from the doctor's negative on a fast plate, so as to secure all detail without too much contrast, and then from this make a print on glossy bromide paper. This should be compared with the original negative, with which it should agree absolutely except for the range of contrast; that is to say, it must show every bit of detail, and if it does it can be used as the original for making the half tone, giving a result that will be surprisingly good. Let it be repeated, the success of this method entirely depends on making the right kind of positive, and it is next to impossible to do this on a process plate.

Exhibitions.

LANCASHIRE MASTER PHOTOGRAPHERS.

COINCIDENT with their general meeting and dinner, the Lancashire and District Society of Master Photographers opened an exhibition of professional work at the Blackpool Art Galleries.

Members' exhibits occupied three walls of No. 1 Gallery, the scheme of hanging simply aiming at symmetry. As would naturally be expected, there was no standard as regards size or style, mounting or framing, the exhibits representing individual ideals in all these respects. Studio and "At Home" portraits occupied one section, artificial light photographs a second, commercial work a third, and coloured pictures the fourth. The common process, as far as the eye could discern, was bromide, and the sizes were from half-plate to 20 by 16.

The gem of this section was a half-plate child study, by Lord, which for attractiveness, truth, and simplicity was excellent. It was worthy of a larger mount and more prominent position. A pair of artificial light studies by Cyril Foley showed style and pose, and were indistinguishable from daylight work. Over-elaboration of background detail, however, somewhat detracted from the importance of the figures. The commercial section was very small, showing only a few interiors and one or two engineering photographs. The most noticeable print here was a good, clear machine-photograph by W. T. Canter.

Prominent in the coloured section was a 30 by 40 canvas of a "Tommy," a life-size half-length by Sarnie.

The members' exhibits were mostly unsigned, and, though numbered, no catalogues were obtainable. The fourth wall of the gallery was devoted to camera studies—many striking and one or two futuristic—by other than Lancashire men. The names of Marcus Adams, R. N. Spaight, W. Blinworth, and Angus Bass, among others, were well distributed, and did much to add a striking note to an otherwise quiet little show.

FORTHCOMING EXHIBITIONS.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

AERIAL CAMERAS.—No. 123,997 (May 13, 1916). The invention relates to aerial cameras, in which the camera mechanism is operated by a propeller or vane rotated by the rush of air due to the passage of the aeroplane or the draught from the engine propeller. The free propeller mechanism first used had the disadvantage that it did not provide for the greater wind pressure when the aeroplane is travelling against the wind than when travelling with the wind, resulting in the camera mechanism operating more quickly and taking more exposures when the

Fig. 1

aeroplane was travelling slowly than when the aeroplane was travelling at its highest speed. It has been proposed to rotate the propeller shaft in a regular and uniform manner by virtue of an inertia control.

The invention is designed to provide means whereby the propeller shaft is free to rotate at any speed according to the wind pressure, while the speed of the camera mechanism driven from the propeller shaft is governed and runs at a uniform speed without regard to the varying wind pressures to which the shaft is subjected.

Mechanism is provided whereby this uniform speed can be reduced or increased at the will of the airman to give the desired number of exposures over any predetermined distance.

The hollow propeller shaft 1, fig. 1, carries a longitudinally moveable sleeve 2 which engages with the friction disc 3 freely mounted on the shaft 1. A centrifugal governor 5 is attached to the disc 3 and to the driven mechanism 6 by the springs 4 so that, when

Fig. 2.

the speed becomes too high, the disc 3 is moved out of engagement with the disc 2. The speed may be varied by the operator by moving the disc 2 along the shaft by means of the rod 14, block 11, and the pin 12 carried by the disc. In a modification, the weights 5 are replaced by the ring 15 attached to the disc 3 by the link 16. The position of the disc 2 may be varied by moving the collar 19 by means of the pins 20 working in the spiral slots 21 in the casing.—The Williamson Kinematograph Company, Limited, and Colin Martin Williamson, both of 28, Denmark Street, London, W.C.,

AIRCRAFT CAMERAS.—No. 123,998 (May 13, 1916). The invention consists in mechanism for aircraft film cameras, whereby the film is firmly held in position during its passage through the camera, comprising a punch adapted to punch a series of holes in the film during its passage through the camera, combined with a feed

claw adapted to give the film a positive travelling motion, said members being so timed that the film is punched at the moment the feed claw leaves the film, while the claw engages in the next feed hole as the punch is released.

In the drawing the disc 1 is mounted on a shaft which is rotated by gearing from a propeller driven by wind pressure. An arm 2 is pivoted on a crank-pin carried by the disc 1, and is guided by a pin 3 working in a slot 4 formed in a plate 5. The slot 4 is shaped so that the claw 8 attached to the arm 2 moves upwards, downwards, and forward in succession, so that it engages in holes in the sensitive film 7 and moves it forward intermittently. The edge of the disc 1 is formed as a cam which acts on the roller 10 carried by the lever 11 so as to actuate the punch 6 just before the claw 8 engages with the film. At the same time the spring 17 moves the sleeve 16 into contact with the film to facilitate the withdrawal of the punch. A needle point 18 is attached to the claw 8 to feed the film forward before sufficient holes have been punched.—The Williamson Kinematograph Co., Ltd., and Colin Martin Williamson, both of 28, Denmark Street, London, W.C.

ENLARGING AND PRINTING EASELS.—No. 124,639 (June 1, 1913).

An easel, according to the invention, comprises a frame, supported in a vertical position, with a hinged back or flap having an arm attached to it which carries a comparatively heavy ball or weight at its end. The front of the frame is of glass, or may be constituted by the negative when the apparatus is used for contact printing, and the weighted arm is so positioned and shaped that the weight tends to keep the flap tightly pressed against the back of the glass.

To insert the paper it is only necessary to raise the ball, using it as a handle to throw the flap back on its hinges. The paper is then slipped in, and kept in place by the flap when it is

Fig. 1.

allowed to return to its closed position under the influence of the weight. The flap may be lined with felt or like material, such as is usually employed on the backs of printing frames. Conveniently the frame encloses the flap on three sides at the back, but one side is left flush with the glass front so that the paper may be drawn out and inserted easily. Provision may be made for the insertion of masks between the glass and the paper.

For contact printing from a negative of smaller size than the frame, a piece may be cut out of the felt or other material forming the face of the flap to constitute a rebate for the negative, and the negative and paper may be placed in position when the flap is open.

Or, again, in place of the glass front of the frame, there may be inserted a carrier or a series of carriers for the smaller negative, the paper being pressed against the negative by the weighted back, as when the easel is used for enlarging.

In the drawings the frame A is supported rigidly in a vertical position on a base B, and is provided with an opening, which is usually covered by a sheet of glass C, which when desired can be removed from the frame. Behind the frame is a back or flap D, hinged near the bottom of the opening and adapted to close in tightly upon the glass C. When in its closed position the hinged back D is surrounded on three sides by strips A¹ fastened at the back of the frame, but on one side, the right-hand side in Fig. 1, this strip is omitted to facilitate the withdrawal of the glass C or of the printing paper. The face of the flap D is covered with felt or like material at D², and the flap is provided with an arm E carrying a weight E¹ so positioned that normally the weight tends to keep the flap in its closed position and pressed with a firm and even pressure on the glass C.

In its normal use as an enlarging easel, a number of duplicate enlargements can be produced very quickly, as it is simply necessary to place the sheet in position on the flap or against the glass, after having lifted the weight E¹ to open the flap, and then to allow the weight to close the flap and press the paper against the glass C. No catches or fastenings are necessary, and as soon as the exposure has been made the paper can be removed after simply raising the weight E¹ again.

For use in contact printing, if the negative is of the same size as the glass C, the latter can be removed and its place taken by the negative. If smaller negatives are to be employed, one or more carriers may be used, the larger carrier fitting into the frame in place of the glass.

Alternatively, a recess D' may be cut in the felt or other

Fig. 2.

material on the face of the flap D to accommodate the smaller negative and the printing paper at the back thereof.

The construction shown is that of the simplest form of easel according to the invention, and no means are illustrated for up and down or tilting movements of the frame relatively to its base. Such movements are, however, well known in printing frame easels, and may be employed in easels according to this invention. Harold Walter Moyne, School of Photography, Royal Air Force, Farnborough, Hampshire

New Materials, &c.

Double Weight Cream Carbon Bromide De Luxe. Made by Thomas Illingworth and Co., Ltd., Park Royal Willesden Junction, London, N.W. 7

A new addition to the grades in which Messrs. Illingworth manufacture their well-known "de Luxe" brand of bromide paper has just been introduced by them, and possesses features which specially recommend it. This "Cream Carbon Surface de Luxe," as it is called, is a double-weight paper—it is made only in double weight—though it may be obtained coated with either the normal or the soft emulsion familiar to users of the ordinary "de Luxe." The feature of the paper is its surface of semi-sheen (described as velvet), in contrast to the smooth matt of the ordinary grade. Such a surface, in conjunction with the cream tint of the paper, confers on the material a quality which is a very close approximation to that of the colloido-chloride papers, of which, in pre-war days, Continental makers were large importers. As regards the replacement of a print-out collodion paper by one of the development type, we think that here for once we have before us a process which has been going on during the last few years quite apart from the circumstances created by the war. The adoption of development papers has been affected very little by scarcity of those of the print-out type and for years past makers have been turning their skill in the direction of combining the enormous convenience and speed of development papers with the quality and general appearance of those produced by print-out printing. Such photographers as still hanker after the effects of certain colloido-chloride papers will turn with satisfaction to this new product of Messrs. Illingworth's, and those who know the firm's goods will experience a confident interest in the new addition. As regards the quality of the prints in respect to colour, gradation, purity of the lights, and freedom from mechanical defects, we need only say that it sustains the reputation of the "de Luxe" paper, and we could not perhaps say anything more in its favour.

Criterion Portrait Bromide. Made by Criterion, Ltd., Stechford, Birmingham.

A new grade of the bromide papers made by the Criterion Company is one which has been introduced specially for the printing of portrait negatives, or, perhaps we should say, for portraiture printing where the aim is the maximum of detail in conjunction with good brilliancy. The new paper is slower than ordinary bromide, but its lesser speed is still one which makes it rapid in use in the customary printing boxes. From our experience we think photographers will endorse all the makers' claims for the particularly good gradation in the shadows and the purity of the whites. The paper is handled in the ordinary way, and gives by direct development an image of pleasant, warm, black colour. It is issued in four surfaces, namely, matt, silky, cream crayon, and glossy, and in each surface is obtainable in single and double weight, and as postcards.

Professional Flash Powder. Made by Messrs. Johnson and Sons, Lt., Cross Street, Finsbury, London, E.C.

Messrs. Johnson and Sons have just placed upon the market a new brand of their flash powder, designed specially for professional use on such occasions where large groups and banquets are photographed by flashlight. The ideal for all such purposes is, of course, a smokeless flash powder, an ideal which has never been, and is never likely to be, realised. Nevertheless, Messrs. Johnson, by means of the use of new constituents in the flash-powder, have produced a preparation which we think is as good as can be made. Certainly it is one which is fully equal in the rapidity of the flash and the thinness and, so to say, "dispersivity" of the smoke to a Continental powder very largely used before the war. A careful comparison test with the new powder against one of the ordinary kind shows that although the smoke at the instant of the flash seems to be very little less than ordinarily, in a few seconds it gains itself and speedily disperses. We imagine that this is due to the much finer state of division of the particles in the smoke, at any rate, the difference is very marked in practical work, particularly where two or three exposures are being made in succession in the same room or hall. It is found that in the case of the new "Professional" powder such successive exposures can be made without any ill-effects on the results with the second, third, or fourth flash, whereas with most ordinary powders the smoke is of a density which calls for a considerable time and thorough ventilation to bring the air into a state for further exposures. The preparation is sent out in the form of two powders, to be mixed just before use, and is supplied with touch paper for ready ignition.

Hard Tropical Hardener. Made by Messrs. Johnson and Sons, Ltd., 25, Cross Street, Finsbury, London, E.C.

A new introduction which, we venture to think, will be accorded a very wide welcome wherever photography is done under tropical conditions has just been placed on the market by Messrs. Johnson and Sons. It is known as the "Hard Tropical Hardener," being manufactured under a patent of the Fford Company. It is a clear liquid with some odour of formaline, which for use is diluted with from 7 to 4 parts of water, according to the degree of temperature at which the photographer is working. In this diluted bath exposed plates are immersed, without previous wetting, for three minutes, and are then given a brief rinse before being developed. The bath exerts an extraordinary tanning action on the gelatine film, so that development may be done with any developer at temperatures up to 110 deg. F. without any of the ill-effects of softening, melting, or frilling which are so difficult to avoid at any temperature above 70 or 80 deg. A test which we made shows the remarkable behaviour of the solution. The two halves of a negative developed with a developer compounded with caustic alkali were immersed one in water and the other for three minutes in the diluted hardener bath. On immersing these two halves in water at 120 deg. F. the untreated half immediately dissolved off the glass, whilst the half which had been hardened remained entirely intact, being no softer than a gelatine film developed in the usual way at the normal temperature of 60 deg. F. Inasmuch as the hardening treatment does not interfere with the action of any developer, it will be seen that workers in the tropics have here a most valuable means of combating an ever

present difficulty. Even at the high temperature at which the developer requires to be used, there is no necessity to rush development, so that, apart from the physical preservation of the film, the use of the hardener necessarily contributes to a greatly improved quality in the negatives. Moreover, the hardened film during drying is protected, through the action of the chemicals in the hardener, from attacks by insects. While the hardener is primarily intended for use in tropical countries, it is easy to see that there will be a considerable demand for it among the photographers in temperate climates whose work is put through in the minimum of time, and whose practice in many cases is to make enlargements from the negatives whilst still in a wet state. It is evident to us from the experience we have had of the Ilford hardener that it provides a means of thoroughly safeguarding a negative at this stage without the need of modifying a photographer's present practice other than the use of the hardening bath before development. The preparation is supplied in 3 oz. and 6 oz. bottles.

OZOBROME MATERIALS.—The Autotype Company, 74, New Oxford Street, London, W.C.1, have now, as we intimated a few weeks ago, taken over the supply of materials for the Ozobrome process from its inventor, Mr. Thomas Manly. It is a step which all users of the process will welcome, since the Autotype Company, with its long and pioneer experience in pigment printing, is certainly the best qualified manufacturing firm to undertake the production of the tissues and transfer papers for the sister process. We are quite sure that all the requisites which they supply will be of the high quality which has constantly characterised their own Autotype products. As a reminder to those who may not be familiar with the Ozobrome process, let it be said that this ingenious method of making carbon prints starts from a bromide print or enlargement, which is simply squeegeed in contact with a sheet of pigment paper soaked in the special Ozobrome bleaching and pigmenting bath. After separation the paper can be developed, after transfer, just like any other carbon print. The avoidance of daylight printing and the production of unreversed prints are features of the Ozobrome process which have proved great recommendations, whilst in other respects it has properties of special value to the pictorial worker.

New Apparatus, &c.

The Dependence Print Washer. Made by J. and R. Oldfield Limited, Warwick Street, Birmingham.

A PRINT washer of a very reliable and efficient type is a new introduction of Messrs. Oldfield, for many years wholesale makers of many of the metal photographic accessories, such as dark-room lamps, optical lanterns, etc., sold by the trade. The washer is in the form

of a perforated cylinder, which is turned in a tank by a water-wheel, the prints contained in the cylinder being thus kept constantly in movement in the water. Moreover, the stream of water from the tap is divided into two parts, one passing to operate the water-wheel and

the other being led into a pipe placed along the length of the tank containing the rotating cylinder. This pipe is perforated with a series of holes, so that when the washer is in operation fine streams of water are directed inside the cylinder, and serve further to cause circulation of clean water among the prints. The tank in which the cylinder turns is fitted with an outlet syphon, so that, in addition to being kept in constant movement, the water in which the prints soak is automatically removed at intervals and replaced by fresh. It cannot be doubted that in these circumstances the washer removes the hypo from prints very thoroughly in a comparatively short time. Messrs. Oldfield, in the course of designing the apparatus, have had tests made proving that the hypo is completely removed from a full load of prints in half an hour. The washer is made in a series of sizes, the smallest being sold at £1 10s., whilst a size suitable for the requirements of the professional photographer costs £7 10s. A still larger size also adapted for handling lengths of cinematograph film is supplied at £9 10s.

Ideal Celluloid Plate Markers. Made by Messrs. O. Sichel and Samuelson, 52, Bunhill Row, London, E.C.

THIS is a folder, made of stout celluloid, for the plate-marking of prints or postcards. The folder consists essentially of a base, to which is cemented a piece of celluloid of the size and shape of the plate mark required. Attached to the base is a second sheet of celluloid provided with an aperture registering with the piece cemented to the base. It will be clear that by insertion of a print between the base and the upper piece a plate mark is readily produced by pressure, whilst the print can be easily placed in the correct position, owing to the transparency of the whole accessory. The sample sent to us is one for the plate-marking of postcards printed in strips of six, and consists of a base measuring 14 by 6 ins., and provided with three raised dies measuring approximately 3 by 5 ins. The postcard strip is plate-marked in two steps, inserting into the folder first one part of it and then the other. The folders are made in all shapes, such as square, oval, with rounded corners, and are specially intended for photographs made on the card-thick nass paper. While moderate rubbing with the hand is ample to impress the plate mark, the folder can, of course, be inserted in any press, such as that used for dry mounting. Full particulars of pattern sizes, and prices may be had on application to Messrs. O. Sichel and Samuelson.

CATALOGUES AND TRADE NOTICES.

CRISTALLOS CHEMICALS.—The old-established French firm supplying ready-made photographic chemical preparations under the trade-mark of Cristallos, sends us its price list in English of a selection of its products. These include a special tropical developer for the development of plates in hot climates, various single-solution developers, toning baths, dye tinters, and mountant. A copy of the list may be obtained free on application to MM. Cristallos, 67, Boulevard Beaumarchais, Paris.

LILYWHITE SERVICE.—Messrs. Lilywhite, Limited, Halifax, Yorks, have just issued a four-page list of their prices for trade-printing, etc., for photographers, such as contact bromide and gaslight prints, postcards, and enlargements. The prices are for "straightforward" work; but Messrs. Lilywhite are always glad to quote for special work falling outside this category.

THE LIGHTWEIGHT TENT SUPPLY COMPANY, 61, High Holborn, London, W.C.1, send us an illustrated price list of their camping outfits, including sleeping-bags and other equipment, of which they have long made a speciality.

THORNTON-PICKARD APPARATUS.—The 1919 price list of the Thornton-Pickard Manufacturing Company, Altrincham, England, appropriately signifies the large share taken by this firm in the provision during the whole period of the war of photographic apparatus for aerial photography, and for the training of aerial machine gunners. It is a sign of the firm establishment of air-machines and aerial photography as military weapons that the company should announce its resources for the supply of such apparatus in the future. The catalogue contains the eloquent appreciation of the work of the Thornton-Pickard Company by Mr. Spencer

Leigh Hughes which we published in last week's issue of the "British Journal," and a further feature of it is a collection of reproductions of official R.A.F. photographs, including an early one which served the invaluable purpose of showing the importance of this system of reconnaissance in military operations. As regards the company's well-known ordinary photographic apparatus, the list specifies the several patterns of shutter and the leading lines in cameras, such as the "Royal Ruby" stand camera, folding metal hand cameras, and reflex instruments. A new model of reflex, named the "Victory," is one of the special Ruby series for 3½ by 2½-in. pictures (6½ by 9 cm.), which, complete with Wray "Lustrar" anastigmat of f/5.9 aperture, is priced at £12. The list describes other apparatus for enlarging, and is one which the buyer of photographic apparatus cannot afford to be without.

News and Notes.

EXHIBITIONS IN 1920.—The series of fairs organised by the Board of Trade will be on a very much larger scale next year as a result of the more or less complete return of manufacturing firms to peace conditions. The Fair will be held partly in London, partly in Birmingham, and partly in Glasgow, each place being chosen in regard to the industries which on the whole are nearest to it. For the first time since the organisation of the Fairs, photographic appliances and equipment, as also optical goods, are to be admitted, the engagements of photographic firms during the war on munitions having precluded their taking part in exhibitions. It is, of course, doubtful whether photographic firms will be largely represented at the Fair, which is to be held from February 23 to March 5, but, however that may be, the visitor to London about this time will also be able to visit the purely Photographic Trades Exhibition, which it is the intention of Mr. Arthur C. Brookes, editor of the "Photographic Dealer," to organise, for the first time after the cessation of hostilities, on the very successful lines adopted in the past. The buyer of photographic goods for sale abroad should therefore obtain exceptional opportunities and facilities for traversing the whole British market with very little trouble in London in the spring of 1920.

HOUGHTON EXHIBITION AT BLACKPOOL.—In connection with the annual general meeting and exhibition of the Lancashire Society of Master Photographers on May 26, an up-to-date and thoroughly British exhibition of goods was held by Messrs. Houghton at the Palatine Hotel, Blackpool, under the superintendence of Messrs. Ibbes and Richard. Of the professional apparatus shown, special notice is due to the new Ensign drying machine and to a rotary beveller, both of which are arranged to run off the same motor, take up surprisingly little room, and are practically child-adjustable and fool-proof. The dryer occupies something less than a square yard, beats itself in ten minutes, and dries (flat) double-weight prints in 2½ minutes. It is strongly built, and needs the minimum of attention. The beveller is small and strong, and attacks a mount with a clean and easy precision that should make bevelling a pleasure. The Ensign printing cabinet for work up to 15 by 12, a neatly-built machine, carrying its own table as drop wings, and the well-known "Pawl" machine, were also in evi-

dence, the working of all being ably demonstrated by Messrs. Ibbes and Richard. Plates and papers were also well in view, both being shown by Ilford, Barnet, and Wellington, and the latter by Kosmos, whose Vitegas prints were in charge of the firm's Mr. Simmons. Notable on the Vitegas table were a set of studies by Fielding, a scrutiny of which well repaid the devotees of development papers. Splendid results were shown on Wellington and Ilford papers, and a set of bromide and gaslight prints by Barnet went far to prove that the artistic possibilities of these papers are practically inexhaustible. A neat set of the chief chemicals used in photography completed a very interesting if somewhat compact display.

MAKING WHITE BACKGROUNDS.—For a long time (writes a correspondent of "Camera Craft") I tried to improve the density giving power of my white background by lighting it as strongly as I could from the front, but doing this often interfered with the desired lighting on the subject itself. Then the thought came to me that I might use a ground more or less transparent and give it added strength by lighting it from behind. The plan was tried with very good success. Of course, one must so arrange matters that the light is thrown on the back of the ground at an angle, as a strong light thrown through the ground in the direction of the lens would not be satisfactory. This, however, is not hard to do, and in my case was achieved by cutting a window in the side wall just back of the skylight where the light admitted flooded the space behind the ground being used for my light background effects.

Correspondence.

- Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- We do not undertake responsibility for the opinions expressed by our correspondents.

PHOTOGRAPHERS' NAMES ON POSTCARDS.

To the Editors.

Gentlemen,—Surely there is some mistake in the imprint of a publisher in the North of England now issuing series of actress and beauty postcards the work of famous London studios. These cards are stamped, "Photo by '—,'" and the name of the firm inserted and not the photographer. Is this not a case for the P.P.A.—Yours faithfully,

Hampstead, N.W.

"FAIR IS FAIR."

REVERSAL IN TANK DEVELOPMENT.

To the Editors.

Gentlemen—I have read with interest the letters in your journal re reversal in tank development, and would like to mention that I have had a similar experience, having four positives and two negatives on one film. A remarkable thing about it is that the four which came out positives were correctly exposed, while of the two negatives, one was over and the other one under-exposed. This film was developed in a dish and not in a tank, as has been the case with your previous correspondents. It would be very interesting to find out the cause of this phenomenon.—Yours faithfully,

REGINALD E. EDGECOMBE.

10, Lune Grove, Moseley Road, Birmingham.

May 28.

(In its way our correspondent's experience is unusual, although reversal appears to be much more common with roll film than with plates. We still hope that there may be among our readers some who can supply the technical particulars as to plate, developer, etc., in such a remarkable case of reversal cited by our correspondent Mr. Binns, of May 16 last, who, it will be remembered, obtained twenty five quite good positives during the tank development of nearly a thousand plates, all exposed on outdoor subjects.—Eds. "B.J.")

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

- E. T. B.—The only gelatinizing firm we know of is Messrs. McCaw, Stevenson, and Orr, Ltd., 31, Shoe Lane, London, E.C.
- R. K.—We thank you for your inquiry, but we have no intention of republishing the present articles by "Practicus" in book form.
- D. W. M.—We give the formula and the instructions (the latter are the essential thing) for making the white dextrine photo paste in the "Almanac."
- M. A.—The only book which deals with methods of colour photography, such as Autochrome and the Paget process, is "Photography in Colours," by Dr. Lindsay Johnson, and obtainable from our publishers.
- G. P.—The usual plan is to let the cards dry on a net only as long as they remain limp, and then to put them in piles under light pressure. It is a help to getting flat cards to print in strips of six and to treat the six-postcard strips as above.
- H. A. F.—The particulars given by the makers are:—Focussing scale graduated in metres (equivalent practically to yards); nearest distance of objects in sharp focus when camera is set at infinity, 16 ft.; shutter speeds are 1-4, 1-8, 1-16, 1-32, and 1-64; lens diaphragms, $f/6.3$, $f/7$, $f/10$, $f/14.4$, and $f/20$.
- H. A.—You should tell us the smallest portraits you want to take, as that is what determines the focal length which you can use. For C.D.V. full-lengths you can use an $8\frac{1}{2}$ -in. lens, but if you do not want to take anything smaller than cabinet full-lengths you can use a 12-in. focus, and this is a very much better choice.
- F. R. S.—For your purpose we can suggest nothing better than two pieces of stout lead wire fixed to each end of the printing frame. You can bend these over at any required height in order to support a vignetting card. Lead wire about $\frac{1}{4}$ in. diameter is amply stiff enough to hold a light card, and can be bent and re-bent into the various positions.
- D. F.—Your simplest and best plan will be to raise the roof entirely on both sides so that the eaves are 8 ft. from the floor. You will then be able to use the ordinary size of backgrounds close up to the side. If your roof is in good condition, you will, naturally, use it; but if not, we should advise you to adopt metallic glazing and avoid drips.
- OBJET D'ART.—Various additions have been recommended for the bleach in sulphide toning, but there is no particular advantage in the use of any of them. You cannot do better than adopt the bleach formula which we give in the "Almanac," viz., ammonium bromide, 100 grs.; potass. ferricyanide, 300 grs.; water, 20 ozs.
- WET-PLATE.—Can you tell me where I can get a book on wet-plate work for a beginner? I want to copy maps, etc. What is the formula?—G. M.
- The best book is "The Wet-Collodion Process," by Arthur Payne, published by Mawson and Swan, Mosley Street, Newcastle-on-Tyne, price 3s. 3d.

W. B.—Yes, it will be necessary to register the business. Apply to Registrar of Business Names, 39, Russell Square, London, W.C.1. There is no restriction on your compounding developers, etc., so long as you do not use any scheduled poisons. The only scheduled poison likely to occur in any photographic preparation is mercuric chloride and mercuric iodide.

K. S.—There is some talk of photographers' associations taking up instruction, but it is all very much in the air at present, and it will probably be a very long time before any such instruction gets organised as well as it is organised at the present time by the Photographic School of the Regent Street Polytechnic, which is the best place your son can go to for training to qualify him for professional work.

M. T.—It is not necessarily the fault of the tissue; in fact, unless the tissue is so bad that it will not adhere properly, we do not see how it can be the cause. Apart from defective trimming, such narrow protruding edging may be caused by the prints not being thoroughly dry and undergoing slight contraction in the mounting press. With large prints like yours the contraction could easily be enough to account for the defect.

G. C. S. (Gottenburg).—The stains have all the look of being due not to developer but to the fixing bath. Although you may have fixed thoroughly, as you think, a cold fixing bath will give rise to stains. We prefer not to expose negatives to white light until they have had at least a brief wash from the fixing bath. Some plates will come to no harm if exposed to light as soon as they are in the fixer, but we think our rule is a good one for general practice.

TRISTRAM.—No retouching can be done on such films, but you should try coating the back (where most of the scratches are) with a solution of fish-glue—that is, fish-glue or seccotine mixed with enough water to make it flow freely. Coat both sides of the film with this, and let the coating dry. It dries glossy and even, and will often fill up the scratches sufficiently to get a presentable enlargement. Afterwards the coating can be easily removed by soaking the negative in tepid water.

B. J.—With a total length of studio of 12 ft. you can only get 8 ft. working distance at the best; this is allowing 2 ft. for operator and camera, and 2 ft. for sitter and background. To get a full-length postcard in this space you cannot use a greater focal length than 6 ins. This is really too short for good perspective; but if your customers are not critical, it might pass. You should get fairly rapid exposures with a total of 4,000 c.p., but we should prefer four 1,000-c.p. lamps to the two you mention.

SUMMARY.

Some notes on the selection of a safelight for the development of different varieties of plate and in regard to the photographer's optical comfort are contained in a leading article. (P. 330.)

A recent paper by Mr. F. F. Renwick before the Royal Photographic Society has very usefully surveyed recent research in the physical and physiological phenomena which affect the problem of the translation of colours into monochrome. (P. 334.)

We publish the questions (and the answers thereto) set in the recent examination held by the City and Guilds of London Institute in pure photography. Those on photo-mechanical processes will appear next week. (P. 336.)

The article by "Practicus" this week deals with the portraiture of elderly people and points out the descriptions of lighting which are suitable for elderly sitters of different types. (P. 333.)

For the production of colder tones by the customary bleach and-sulphide method the Rajar Company recommend the treatment of the prints, previous to bleaching, with a weak bath of ammonium sulphide. (P. 338.)

For the photography, with a vertical camera, of small articles such as parts of a machine, an American worker uses a semi-transparent horizontal easel which can be illuminated on its under side, and so gives an improved shadowless rendering of the objects, whilst avoiding the necessity of all blocking out. (P. 338.)

In a contributed article Mr. D. Charles deals with the elements of the movements of a camera. A succeeding contribution will have for its subject the specific uses of the various movements. (P. 331.)

At the Edinburgh Society of Professional Photographers last week Mr. Robert Burns, A.R.S.A., delivered a lecture on composition in portraiture, illustrating his remarks by blackboard skeleton drawings of paintings by Sargent. (P. 341.)

A folding focal-plane camera for roll-film, in which the winding of the shutter also winds the film for successive exposure, has been patented. (P. 339.)

The darkening of proofs on untuned and unfixed P.O.P. is frequently a cause of sitters' dissatisfaction with a portrait. (P. 339.)

EX CATHEDRA.

Acknowledgment. We have to thank many correspondents, comprising both subscribers and those engaged in the photographic apparatus and materials trade, for their letters of congratulation upon the "B.J. Special" issued last week. We are glad to re-echo the note of many of these letters—namely, that the issue is a kind of outward and visible sign of the days of peace for which the world has waited so long. At any rate, if one cannot write "peace" as characterising the state of Europe, nor even disregard the continuance of the prosecution of warfare in some parts of it, an issue such as that of a week ago certainly marks the spirit of confidence which animates the photographic trade as a whole and stimulates it in its combat with the many difficulties which still present themselves. Our readers overseas will have had an opportunity of judging of the multiplicity and many activities of firms engaged in the supply of photographic requisites in this country, in which list, let it be mentioned, are a few firms in France who thus have first addressed themselves to English-speaking users and buyers. We may hope that this overseas number of the "British Journal" is the first of a new series which will maintain and exceed the success of those published in the years before 1914.

Proofs.

Whatever may be the commercial advantages of employing untuned and unfixed P.O.P. prints as proofs, there are, we think, drawbacks which more than counterbalance them. The caution may be given, both personally and in writing, to examine the proofs only in weak light, yet the natural tendency of the public is to disregard this advice altogether. One may see a sitter being handed a batch of sensitive proofs in a reception room to the accompaniment of the usual caution, and as often as not the proofs will be scrutinised in broad daylight as soon as they are taken out into the street. Very likely they will be brought back the next day with the complaint that the sitter's friends do not think that the portraits are good. In such circumstances as these it is common experience that a proof on bromide paper will evoke the opinion that a greatly improved result has been obtained. We think that the advisable course is to finish proofs roughly, either on P.O.P. or bromide, so that there is no chance of immediate fading. They may be defaced by other means, so as to defeat the purposes of unscrupulous people who may try to get something for nothing, but it requires to be recognised that a proof is examined not only by the sitter, but by others of the family, and that therefore is bound to be exposed to more light than an untuned and unfixed P.O.P. will stand.

Focussing V.P. Cameras.

At the present time there is a decided tendency upon the part of many photographers to use the vest-pocket camera under conditions where its short focus and large-aperture lens may be employed at its fullest advantage without recourse to stopping down. A short experience with these instruments will readily prove what a simple matter focussing really is. Even when a lens working at $f/6$ is employed, such a camera is practically a fixed focus instrument, as a simple depth of focus calculation will readily prove. If a 3-in. lens is employed, working at $f/6$, all objects from about 12 ft. 6 ins. to infinity may be assumed to be sharply focussed, while a very slight variation of the focussing scale will have the effect of giving fine definition over nearer and less distant objects over a long range. If the focussing scale is accurate, experience has taught us that it is far more satisfactory to rely upon this, together with a direct-vision view-finder than upon examining the image upon the tiny focussing screen. Much of our own work has been done upon roll-film, and we never remember feeling the lack of a focussing screen, nor were the negatives anything to complain of as regards sharpness.

* * *

The 1919 Salon.

The prospectus and entry form of the forthcoming London Salon is now obtainable from the honorary secretary, Mr. F. J. Mortimer, 5A, Pall Mall East, London, S.W.1. The exhibition will be held from September 13 to October 11, and the last day for receiving pictures at the Pall Mall Gallery is Tuesday, September 2. Special emphasis may be laid upon the condition that no pictures are to be framed. Those sent by exhibitors in the British Isles may be mounted, but contributions from abroad must not even be mounted. As in the last two or three years, it is the intention of the Salon Committee themselves to arrange for the display of the pictures under glass, according to a scheme which has been successful in ensuring a pleasing appearance of the walls as a whole. This policy will be assisted if exhibitors as far as possible will employ mounts of one or other of the sizes 15 x 12, 20 x 16, and 25 x 20, in no circumstances larger than the last named. Wherever possible a white or light-tone mount is preferred. An entry and packing fee of 3s. is charged to each intending exhibitor, this amount covering any number of pictures.

* * *

Panchromatic Negatives.

Many photographers fail to obtain the most satisfactory results on panchromatic plates through omitting to give sufficient exposure. It is a fact not generally realised that in order to obtain a satisfactory rendering of the more difficult photographic colours, such as dark reds, greens, yellows, etc., ample exposure is essential, in order for them to be fully impressed upon the emulsion. Another misconception also exists as to the type of negative most to be desired. Panchromatic plates will be found to give negatives rather different looking from those on ordinary brands, due to the fact that they contain a far wider range of tone. In order to obtain the full advantage of these tones the negative needs to be developed in order to bring out its full range of tonal qualities. It is a good plan to develop slightly further than would be the case with the ordinary emulsions in order to bring this about, though care must be taken not to carry the operation too far, or the snowy effect, almost like over-correction, which is sometimes encountered in panchromatic work may be met with. As a means of

securing the best results, development by the tank method, using a time and temperature system, has much to recommend it.

NOTES ON THE SELECTION OF DARK-LAMP SAFE-LIGHTS.

AFTER all that has been said and written on the subject, it is rather remarkable but nevertheless true that many photographers, amateur and professional, still regard the safety of their dark-room illumination in terms of dimness, with little regard to the spectral quality of the light transmitted by the window of the lantern. Other things being equal, naturally the dimmer the light the safer it will be, but a comparatively bright light may be perfectly safe for the usual period plates are exposed to its rays, whilst a far dimmer light may have a distinct tendency to cause fog. The plate-maker certainly does use a very feeble red illumination, otherwise the margin of safety from fog allowed to the photographer would be lessened owing to the cumulative action of light.

The familiar canary and ruby fabrics, on the market now for many years, are useful in some cases, but they materially cut down the general illumination, and the former is not to be advised for rapid plates. As they are loaded with coloured materials, if subjected to much handling, a crop of pinholes in course of time appears. Not a few employ ruby glass, which, if deep, also reduces the illumination seriously, and, what is far worse, often permits a miscellaneous transmission at the violet end of the spectrum. It is really astonishing how much blue some commercial ruby glass does let through, whilst other samples have been found satisfactory; but as the eye cannot detect one from the other, unless a spectroscope is available, ruby glass is better avoided unless it can be combined with a yellow or orange screen, known to cut off the blue and region beyond it, including the ultra-violet. Perhaps the "ultra-violet" is somewhat in the nature of a bogey with such lantern illuminants as oil, an ordinary gas jet, or carbon glow-lamp, if otherwise with incandescent gas and in particular metallic filament lamps. With daylight the question of ultra-violet absorption is of importance, and many yellow dyes cutting the blue and violet, transmit an appreciable amount of ultra-violet.

To the busy professional the making of safe-lights is not a practical proposition, and unless the requisite dyes are at hand their purchase at present prices will effect but little saving, even if the labour involved is not considered. Speaking generally, it may therefore be said that safe-lights are better bought and not made, and apart from any question of cost, when purchasing the commercial article we have an assurance that dyes are employed giving the maximum safety for a given amount of light.

The only point then to consider is what particular safe-light to select. With panchromatic plates no question arises, as every prudent worker will follow the direction of the plate-makers. Occasionally it has been thoughtlessly assumed because a particular green safe-light is advised for panchromatic plates that a green safe-light designed to be used with "ordinary" plates will be suitable for the so-called yellow sensitive ortho' plates. But as these record yellows mainly by the green contained in them, a ruby light for these plates is obviously to be preferred. The panchromatic special safe-light is adjusted to transmit a narrow region of the spectrum to which the plate has merely lessened sensitiveness, and the extreme feebleness of the illumination is the chief protection against fog.

For slow and medium speed, and for ultra-rapid "ordinary" plates, the purchase of safe-lights respectively designed for such will also be safe, but this may mean the selection of a red or ruby for the latter, which to many

eyes is tiring, and to some actually distressing. In one case met with, the photographer experienced partial blindness when working in a ruby light for some time, though no ill-effects were felt with a yellow-orange light; probably due to the percentage of green transmitted. Not without reason, commercial safe-lights are designed to be reasonably fool-proof, and therefore err well on the side of caution. It sounds like a "fisherman's yarn," but some years ago a cheerful soul purchased a panchromatic safe-light, and with great confidence in the appellation celebrated the occasion by installing a small electric arc in the dark-lamp. The illumination was extremely good and the fog pronounced.

The choice of a safe-light, considered with regard to such comfort of the dark-room operator as is consistent with a sufficient degree of safety, is therefore of real importance, but one often neglected. No general rule can be laid down, so much depending upon the conditions—intensity of illuminant, method of working, etc.—but it may be said that an orange safe-light listed for slow and medium speed "ordinary" plates will be found quite safe for ultra-rapid plates if they are not unnecessarily exposed to the light. Obviously, if tank development be employed, a far brighter light is permissible than when constantly inspecting progress of development. If green-sensitive ortho' plates are only occasionally used, a sheet of ruby glass, or piece of ruby fabric placed in front, will make a satisfactory substitute for the appropriate commercial article.

Some time ago an enthusiastic amateur, writing in an American periodical, strongly recommended a certain ortho' plate, one reason given being that it could be developed in a yellow light. This was rather a back-handed compliment to the plate in question, but it is a fact that with care plates can often be developed without fog under conditions which may appear highly dangerous. In one instance a safe-light for slow bromide and gaslight papers in front of an incandescent gas jet had to be employed when developing plates of extreme speed. They were, naturally, kept carefully shielded until towards the end of development, but were then held up close to the window to enable density to be judged. Possibly latent fog was induced, but

had insufficient time to develop up in the short period which elapsed between inspection and fixing; at any rate no perceptible fog appeared in the fixed negatives.

Although it has been suggested that as a general rule it is better to purchase safe-lights instead of making them, yet there are always some who pride themselves on employing home-made articles so far as possible, and no one will quarrel with the spirit which animates the mechanically minded fraternity. In the present case the manufacture of safe-lights certainly presents no mechanical difficulties, and precise instructions for making them appear each year in the "B.J. Almanac." These, however, deal with measured quantities of gelatine and dyes applied to the glass, and our experience is that comparatively few will go to the trouble of coating.

A safe-light we have used for years, capable of withstanding a hot lantern, consists of two waste negatives from which the silver had been removed by a strong permanganate reducer, followed by a bath of sulphite of soda (to remove stain), and the usual wash; the gelatine being then dyed-up with a 15 grain to the ounce solution of tartrazine, one of the best yellow dyes for the purpose. They were bound together with a sheet of paper, similarly dyed, interposed. In front of an 8-c.p. carbon filament lamp the light appears of distinct orange hue, though not approaching what would be generally considered as "orange-red." Many have expressed surprise that a bright light of such a character is permissible, yet used with reasonable care it has been found perfectly safe with the fastest plates of "ordinary" brand. The gelatine was varnished as a measure of precaution rather than necessity, and the paper employed, very absorbent and fairly translucent, was that sold for manifold typewriting. Tartrazine is a pre-war dye of Hun origin, but "acid-yellow 72910" of the British Dye Co. is stated to be its equivalent, and we have little doubt it will answer the purpose satisfactorily, as may indeed other yellow dyes. For ortho plates a sheet of ruby glass can be placed in front or, if not at hand, another waste negative can receive the preliminary treatment mentioned, and is then dyed up with methyl-violet, about three grains to the pint. If dyed too deeply little light will pass.

CAMERA MOVEMENTS.

OCCASIONALLY, even in this twentieth century, amusement is caused among photographers by the naive surprise of some people at the total absence of "works" inside even the most expensive camera. For all that it may truly be said that many experienced photographers do not clearly understand the object and use of the various "movements" which usually are all outside the camera. Many produce good results by a sort of instinct acquired rather as a result of long practice than by exact knowledge of how and why a particular adjustment will achieve a desired object. Knowledge of these matters must obviously save a beginner in photography much trouble as well as many plates, and later on will enable him to tackle difficult problems by reasoning out in a logical manner the best and proper procedure to follow, instead of the unfortunately rather prevalent "hit or miss" methods.

There are several distinct moving parts which may be employed separately or in combination to achieve specific objects, and they are quite easy to understand if examined and experimented with one at a time in a systematic and leisurely manner without using any plates at all. In fact, I advise anyone buying a camera to try all its movements carefully in this way before exposing a single plate. I do it myself with every camera I have occasion to use, although (or perhaps it is because) I've been over twenty years "at the game."

Before even trying the "movements" there are a few preliminary facts to be digested, and I put forward also a few suggestions that will be found to make easy the study of the camera's "works." The lens and the ground-glass are the principal parts of the camera. The lens has all sorts of peculiarities, most of which are best left alone by the beginner for a time, but its purpose is to throw such rays of light as reach it from each point in the "subject" to a corresponding point on the ground-glass. The purpose of the ground-glass is to allow the photographer to see whether the lens is doing that or not. The camera bellows and body are to keep all other light off the ground-glass except that which comes through the lens. The "movements" of the camera serve the purposes of adjusting the positions of the lens and of the ground-glass towards one another and holding them in such positions, as well as enabling the ground-glass to be replaced very exactly by a sensitive plate held in a dark-slide. The various adjustments are necessary, because to have the lens fixed "pointing straight" at the centre of the plate, as in a magazine hand-camera, does not suit every subject. A cap or a shutter is for the purpose of admitting light through the lens to the plate for a definite time.

All these things may seem so obvious when put into words that the reader will perhaps wonder why I waste space on them.

Yet it is essential that the fact be grasped clearly that it is the lens that does all the "work." The "movements" merely permit one to take advantage of, or control, its various properties or peculiarities.

Before examining how they do this, the suggestions I mentioned as desirable are that the ground-glass should be smeared over with a trace of vaseline, which is then rubbed off again as much as possible. This allows the "image" to be seen more brightly. Next that a small (but not too small) spirit-level be obtained as well as a set-square, or any piece of flat stiff material cut accurately to a right angle. The remaining need is for a focussing-cloth. This is to wrap round the back of the camera and the observer's head, so that light is excluded and the image on the ground-glass clearly observed. Its essential points are that it must be opaque, not too heavy, and ample in size. These qualities are best filled by a double thickness of black "sateen" a yard square. Two yards of this material, folded once and the edges hemmed, make an ideal focussing-cloth. With these points and needs made clear we are in a position to examine and study any camera with ease in all its details.

Camera Parts and their Movements.

When the reader sees by the list below what a great variety of adjustments there are that may control the respective positions of the lens and ground-glass, he will realise why I emphasised by a whole preliminary paragraph what they are really for, before plunging him into detailed explanations of each movement. Every stand-camera has some of these movements; few, if any, have them all.

The four main portions of the camera are.—The *front*, carrying the lens; the *back*, with ground-glass and grooves for replacing this by a plate held in a dark-slide; the *bellows*, which connect the first two and keep all outside light from penetrating, while allowing the parts to move freely; the *base-board*, which acts as a support for the other parts and may itself be fastened upon a tripod or other stand. When set up in a normal position both the front and the back should be at right angles—both vertically and horizontally—with the base-board, and therefore quite parallel with one another. This is easily tested with the set-square, and if the camera as bought is found not true in this respect marks should be made so that the parts can be set up correctly and fixed so at any time subsequently. Taking each of the parts separately the list of useful movements is as follows:—

FRONT.

Rising (and Falling) Front.—Sliding up and down.

Cross Front.—Sliding sideways.

Swing Front.—Pointing lens up and down.

Side Swing.—Pointing lens to one side or the other. (This movement is rarely provided on a camera, but can generally be improvised when required.)

BACK.

Reversing Back.—Allows ground-glass to be placed "up-right" or "across." The former is mostly used for portraits, and the latter for landscapes, and is often termed "landscape-way" of the plate.

Swing Back.—Swinging towards or away from the front, pivoted either centrally or at the bottom.

Side Swing.—Same remarks as side swing on front, but is usually found on studio cameras, and on many fixed cameras.

BASE-BOARD.

Adjustable Extension.—Sliding movement to allow of varying the distance between the front and the back. This may be a single slide either of the front or the back.

Preferably the camera should have a "double-extension," i.e., an inner frame sliding forward and carrying the front with it on turning the milled knob of a "rack-and-pinion." This allows the lens to be carried further from the plate than

a single-extension camera, which latter is very limited in scope. A "triple-extension" allowing of still longer distance between front and back is still more useful, provided that the camera is not so flimsy as to wobble or sag when extended.

Turn-table.—This is a revolving metal ring to which the legs of a tripod are attachable. If this is not present there should be a screwed "bush" for attaching to an ordinary tripod top by means of a screw.

BELLOWS.

These have no special adjustments, being flexible, but in long-extension cameras it is usual for there to be rings attached to folds near the middle for supporting the weight of the bellows at short extensions, and so prevent sagging into the path of the light from lens to plate.

Lens and Diaphragm.

The lens itself has one moving part that should be explained before going into the adjustments of the camera body because it does more to affect the image than almost any other item, and the other movements are always considered in conjunction with this one. That is to say, the other adjustments will either help or hinder the work of this essential one. The part referred to is the "diaphragm" of the lens, a device for making the aperture of the tube larger or smaller. It may be a wheel with holes of various sizes or a set of plates also with different sized holes to slip into a slot, but most lenses nowadays have a built-in "iris diaphragm" which opens and closes on turning a ring or pointer.

Let the camera be set up with front and back "normal," i.e., at right angles to the base and the lens as central as possible with the plate, opening the lens diaphragm or "stop" as far as it will go, and pointing it towards some brightly lit objects. On moving the lens or the back to and fro while the observer's head is under the focussing-cloth an image will be seen on the ground-glass more or less distinctly. Here let me warn the beginner to keep his head well back and to look at, not through, the ground-glass. The sliding to and fro is called focussing, because one brings to a focus, or sharp point, the image on the ground-glass of part of the subject seen. All the subject will not become sharp at one time, because parts which are at different distances require different lengths of extension between lens and plate. The further away the object the shorter the extension required. Beyond a certain distance all things seem sharp without altering the focus, but with comparatively near objects a great deal of movement is required between the points at which the camera gives one object sharp or another. Although this is elementary, I should like to ask the reader to carry out a sort of practical exercise at each stage, even if only to satisfy himself that what I say is true. Reading alone will not fix things in the mind, and I want to get the elementary points well home so as to make it easier for the student to get hold of things that may seem a bit more complicated and not so obvious later on.

When the "focussing practice," as perhaps I may be allowed to call it, has been tried on several different subjects, distant, near, and near and distant combined; when the sort of images produced by these with the lens at "open aperture" have been observed and carefully compared, as well as the various lengths of extension, preferably by means of actual measuring, let one of the "near-and-distant" subjects be focussed on a point about a third of the distance back from the nearest principal object to the furthest one. Then while looking at the image close down the lens aperture, and it will be seen at once how other objects besides the one most sharply focussed become sharp also. At the same time the image becomes much dimmer all over because less light is allowed through. Therefore in exposing a plate more exposure is needed to make up for the weaker light.

This simple example is put forward not only for the knowledge of the direct effects of "stopping down," as reducing the size of hole is termed, but to show that photography is all through a matter of compromises. As a rule you cannot have a large aperture for short exposures and sharpness of varying distances at the same time. The latter quality is called "depth of focus," and is increased by using a smaller aperture. The meaning of the numbers of the apertures will be ex-

plained later, as they are for use in estimating exposures. Any want of sharpness in the image, due either to the lens itself, or to the use of the various movements of the camera being brought into play can be partly or wholly overcome by stopping down. Sometimes these movements are used to prevent the need for using small stops, where short exposures are essential. These will be taken one by one and explained fully in subsequent articles.

D. CHARLES.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).
The Postcard Studio (March 14).
The Printing-Room (March 21).

About the Reception Room (March 28).
Home Portraiture (April 4).
Portable Studios (April 11).
Copying (April 18).
Handling the Studio Camera (April 25).
More About Lenses (May 2).
Enlargements (May 9).
Advertising the Studio (May 16).
Mounts and Mounting (May 23).
Business Methods (May 30).
Photographing Children (June 6).

PORTRAITS OF ELDERLY PEOPLE.

It is bad form now to talk of old people, so that I have gone as far as I dare, and only describe the class of sitters I deal with this week as elderly, and with these I do not class the lady immortalised by W. S. Gilbert, who "might very well pass for forty-three in the dusk with the light behind her." People who have left the fifties behind may still possess a large reserve of strength and activity, but unless artificial aids are freely made use of carry their age in their faces, and present a different set of problems to the photographer from those which he meets with when photographing those who are still youthful or in what is commonly called the prime of life. Fortunately, most are conscious that they are no longer young, and do not demand the same class of picture as they would have done at an earlier stage in their lives, so that the photographer is at liberty to deal with them so as to produce a good portrait rather than to endeavour to make a "pretty picture," and as nearly all have more or less picturesqueness or dignity this should not be difficult.

One of the greatest errors that can be made is to endeavour to obliterate the traces of time and to produce a picture which is neither like the sitter is nor was at any previous stage in his life; but, on the other hand, the photographer must make the best use of his opportunities, and not make the evidences of age more apparent than he can help.

The first difficulty to be met with is, of course, the colour and texture of the skin, and under this heading I include wrinkles. It is a good plan to start with the determination to leave as little as possible to be done by the retoucher, securing, by judicious lighting, appropriate lenses, and colour-sensitive plates, a negative which should be almost satisfactory without any handwork upon it. Most elderly folk have more character in their faces than young ones have, and therefore we may start with a softer, more diffused light, without danger of sacrificing the necessary relief. Although I do not, as a rule, care for dividing the light into two parts, with this class of sitter it is sometimes advisable to do so, using a good deal of rather low front light to illuminate the

wrinkles, and then admitting a small amount of top light nearer the sitter to give the necessary modelling. This lighting will also be helpful in the case of deeply set eyes and hollow cheeks. When using artificial light the best results can often be obtained by using only reflected light or a combination of reflected and direct light, such as is provided by the enclosed arc and Jobson reflector. What we have to avoid is the production of a "railway map" effect which has to be retouched out of all knowledge before it is at all acceptable. There are some old people with faces of the "Pickwick" type who can be photographed without special treatment, but they form a small minority and do not make nearly such interesting portraits as those with features of a more rugged type.

Next in importance to lighting comes the quality of definition given by the lens. There are many lenses which would have been pronounced "bad" a few years ago which are excellent for our special purpose, for they are incapable of giving sharp definition, and take the edge off the lines and wrinkles in a very satisfactory way. It has in my time been my fate to be photographed by many of my friends with almost every type of lens, from the Bergheim to the most carefully corrected anastigmats, and I must say that I much prefer the "soft focus" results, provided that they are not too soft. The avowedly soft-focus lenses, such as the Bergheim and the Portland, tend to give too much diffusion in small sizes to be pleasing to most people, and I therefore recommend the use of a portrait lens such as the Dallmeyer, Cooke, or the more recent models of Ross as being most suitable for general use. With these any desired amount of diffusion can be obtained by increasing the separation as directed by the makers, but I would recommend anyone starting to use one to make a few trial exposures, noting on each the degree of unscrewing which has been done. It is not easy for one accustomed to sharp images to judge the printing quality of the diffusion by looking at the image on the ground glass, but if we have a set of negatives marked half-turn, one, two, or three turns, we can adjust our lens to one of these focus

as sharply as possible, and make sure of our result. If such a lens is not to hand, a very good substitute may be found in the front combination of an ordinary Petzval portrait lens, which gives a very pleasing softness, obtainable in two degrees according to the position in which it is used—that is to say, that if used with the convex side turned to the sitter a less degree of diffusion will be obtained than if it is turned round so that the flat side faces the sitter, but this is not a discourse on soft-focus lenses, and I must pass on to other points, prominent among which comes the question of the colour of the skin.

From various causes most people lose the pink and white of youth at a comparatively early age, and by forty the majority have taken on rather a non-actinic tint. This, of course, tends to accentuate the depth of the shadows and to make it difficult to illuminate the face properly. Moreover, in healthy subjects there is often a mottling of the skin with little red veins and patches, which, while not displeasing to the eye, give a very rough and uneven effect in the negative when ordinary plates are used. For this reason I strongly advocate the use of orthochromatic plates in conjunction with a yellow filter, which reduces the colour contrasts to a minimum. Even better results may be obtained by using panchromatic plates with a K2 filter, which practically eliminates all the rough effect caused by red veins and yellow patches on the skin, and give images which hardly need any retouching except to modify the features or to correct the outlines; they also give an excellent rendering of faded blue or grey eyes, which usually appear as too light in the print. I have used the red filter of a trichrome set, but this gives an over-correction, and by practically eliminating all colour contrasts in the face gives an almost marble-like rendering. It may be feared that the exposures may be unduly prolonged by using a filter, but this is not so serious an objection as might be anticipated. Granted that a filter will require double the exposure being given, this can be overcome by using a larger stop and being more careful in focussing. Moreover, elderly people are usually good sitters, and will generally stand double the exposure usually given without moving, especially as the poses are almost always sitting ones.

Bald heads and white hair call for a word or two. Both

need a little local shading, and for this a small head screen is useful, care being taken to place it so as to cut the light off the top of the head only, without interfering with the lighting of the features. The screen should be very thin—fine lawn being the best material, and this should be quite clean, so as to obstruct the minimum of light.

Spectacles are sometimes troublesome, and often preclude the choice of poses, but reflections must be avoided, as no matter how skilfully the eye is spotted-in, the effect is never quite natural. I would caution anyone against adopting the old dodge of using empty frames instead of retaining the ordinary glasses. Most spectacles either magnify or diminish the size of the eye, and friends become accustomed to this appearance. When the glasses are absent the effect is altered, and, in addition, the loss of them causes a strained expression, as the sitter can no longer see clearly. If the lighting can be managed without using a reflector, the risk of getting reflections in the glasses is minimised.

I have already mentioned the desirability of reducing retouching to a minimum, and this must be judiciously applied, the all-over style of working being very objectionable. The pencil should only be used to soften lines and spots, not to obliterate them. In many cases, especially with large heads, a piece of celluloid or even a very thin glass placed between the film side of the negative and the paper when printing will give a pleasing softness which takes the sharp edge off the definition, and saves much work.

Many of the most successful portraits of old people are those made "at home." The sitter is spared the effort of visiting the studio, and generally is in a more comfortable frame of mind among their usual surroundings. With the rapid plates now obtainable quite short exposures may be given in an ordinary room, especially when a good $f/4.5$ lens is used. Going out in this way means extra time and work, but I do not believe in making any considerable additional charge for it, providing that a decent order is given. Very often in such cases it is the last, if not the only, portrait the sitter has had taken, and re-orders, some perhaps for enlargements, miniatures, and the like, will probably come in, so that nothing should be done to discourage such business if the opportunity of doing it is offered.

PRACTICUS.

COLOUR VALUES IN MONOCHROME, AND A NEW VIEWING FILTER TO ASSIST IN OBTAINING THEM.

[The following paper, read by Mr. F. F. Rowick before the Royal Photographic Society, deals with a problem which is always present in the translation of colours into monochrome. The author's exposition of recent research will help to make clear the complex nature of the problem and the orthochromatic writer will welcome the promise of more definitive methods which is contained in the latter portion of the paper.—EDS. "B.J."]

My object in the present communication is to invite your attention to the bearing of certain researches on colour-vision upon the problems which confront both artists and photographers when attempting to translate the colours of a scene correctly into monochrome. It is, of course, impossible to convey any impression corresponding to the colours or hues themselves by mere variations in depth of tone in monochrome; our endeavours must, therefore, be limited to the rendering of the brightness or luminosities of these hues in their correct relative relationships.

The average person's judgment of the correct sequence of the luminosities of a number of different colours is so untrained that usually it is only the most obvious falsities of rendering in an ordinary photograph which cause comment. The majority of us are unfortunately too easily satisfied in this matter. Most artists, however, possess a very keen appreciation of colour values, which enables them to agree, with but slight divergencies, upon the relative tone values of any coloured scene. This faculty, which is

largely the result of trained observation, is really common to most of us, and only requires educating.

If photographers are to deserve the commendation of our best artists for the truthfulness of their monochrome renderings of colour, something superior to the unconsidered use of a colour-sensitive plate and a yellow filter will be necessary.

The subject naturally divides itself into two parts: on the one hand we require to know something of the peculiarities of human colour-vision, while the colour-sensitiveness of photographic plates and the proper use of correcting filters constitute the other part.

I shall assume that everyone knows that the brightness or luminosity of a colour is no criterion of its power in other ways (its effect on a photographic plate, for instance). The only reliable means we possess of comparing and measuring the powers of differently coloured lights is to convert them by absorption completely into heat and measure their heating effects, as may be done, for instance, by means of a thermopile and sensitive galvanometer.

When such measurements are made it is found that there is no simple connection between the powers and the apparent brightnesses of two different colours, a conclusion which will not surprise any photographer.

Moreover, as everyone is aware, the appreciation of colour is a somewhat variable faculty. Some unfortunate people are quite blind to certain colours, many have slightly defective colour-vision, and in the light of recent work it is not too much to say that it would be surprising to find in an assembly of twenty or thirty people more than half-a-dozen in whom colour-vision was truly identical.

Apart, however, from these differences between individuals, the eyes of one and the same observer vary in colour-sensitiveness according to the manner in which he uses them.

If a bright multi-coloured object be examined from a distance of 10 or 12 ft., and a careful estimate is made of the sequence of luminosities it displays, and it is then studied anew at a distance of only 12 to 15 ins., it will usually be found that the sequence is no longer the same, especially in regard to the position in the scale of the blues which, to most people, become markedly brighter as the object is brought near.

In consequence of this complex character of our colour sensations much time has had to be devoted to the examination of a large number of persons before arriving at the characteristics of average or so-called normal vision.

It would take too long to discuss in any detail the structure of the eye, so I will content myself with stating that in the critical examination of a small or distant object the image formed by the lens falls on a very small area of the sensitive layer known as the retina. This small area is a tiny depression known as the fovea centralis, which is completely filled by the image of any object subtending an angle of 3 degrees. It lies at the centre of an oval area known as the macula lutea, or yellow spot, which is overlaid with a brownish-yellow pigment, and subtends an angle of about 6 degrees in its longest axis and 4 degrees in its shortest. In the ordinary direct but not critical examination of things we employ this larger area. (A cabinet photograph about 5 ft. distant would approximately fill the yellow spot.)

Outside this central region of clear vision lie those parts of the retina which receive the hazy impressions caused by outlying objects. The important fact to notice is that we form different impressions of the relative luminosities of a series of coloured objects according to the part of the retina on which the image falls, and it is therefore necessary first to decide on the particular mode of examining things which is to be regarded as normal before any more exact relations between colours and their tone values in monochrome can be agreed upon. It seems, however, obvious that since the macula lutea or yellow spot includes the whole region of clear vision within which careful comparison is possible without movement of the eye, it is the colour-sensitiveness of this area that we must take as our standard.

Now since the spectrum of white daylight includes light of every wave-length to which the eye is sensitive, it is clear that all visible colours may be regarded as white light minus one or more of its constituents; and since it has been experimentally proved that the luminosity of every colour is equal to the sum of the luminosities of its components, it follows that if we know the relative luminosities of all the colours of the spectrum the relative luminosities of all other (compound) colours depend only on their spectral compositions. For us photographers the important conclusion follows that if we can make a combination of colour-sensitive photographic plate and correcting filter which will correctly record the relative luminosities of every component of the spectrum of daylight, then the same combination will be able correctly to record the tone values of all coloured objects.

Since there is no such thing as a standard of whiteness and our various light-sources differ considerably in the colour of the light they emit, from the bluish white of bright summer daylight to the yellowness of the paraffin flame, it will be evident that the relative luminosities of a range of colours varies widely with the kind of lighting employed, a fact with which you are no doubt familiar, so that a rendering in monochrome of a multi-coloured object can at best only be strictly correct for a given illumination. If, however, our combination of plate and filter records quite correctly all colour values by daylight, it must also record them correctly (though

differently because they are different) by arc light or by any other illuminant.

Note.—Our eyes possess a certain power of accommodation by which we tend always to regard the prevailing illumination as our standard of whiteness and fail to appreciate the magnitude of the colour differences between one illuminant and another unless a direct comparison is possible. Whether this phenomenon, which constitutes a species of partial insensitiveness to the dominant hue of the prevailing illumination, also affects, to any appreciable extent, our judgment in determining the relative luminosities of differently coloured objects, I have not yet been able to establish. If so, and it seems likely, then it would not be possible to devise a combination of plate and filter which will give equally true records for a wide range of illuminants.

We will now glance at the results obtained by scientific workers concerning this problem of the relative visibility of the different regions of the spectrum.

Since the early work of A. Koenig, Sir William Abney and Professor W. Watson have done a great deal of work on colour-vision in this country (Abney's book, "Researches in Colour Vision," Longmans and Co., is a valuable summary of most of their work), while very exhaustive researches have been undertaken in recent years in America by H. E. Ives, P. G. Nutting, and others.

See particularly H. E. Ives, "Phil. Mag.," December, 1912, p. 853; W. Watson, "Proc. Roy. Soc.," 88A, 1913, p. 404; P. G. Nutting, "Trans. Amer. Ill. Eng. Soc.," IX., 1914, p. 633, XI., 1916, p. 1; Hyde and Forsythe, "Phys. Rev.," July, 1915, p. 70; Troland, "Trans. Amer. Ill. Eng. Soc.," XI., 1916, p. 956; Coblentz and Emerson, U.S. Bur. of Standards Sci., Paper 303; I. G. Priest, "Phy. Rev.," Vol. XI., p. 498, June, 1918.

The final conclusion reached as the result of all this work is that for bright illuminations the retina of the normal eye in the region of clear vision is most sensitive to light of frequency 541×10^{12} vibrations per second (equivalent to wave-lengths $555\mu\mu$), the

Fig. 1.

sensitiveness falling off asymmetrically on either side of this frequency in accordance with the following empirical equation:—

$$V = e^{-0.0002664 (f-541)^2}$$

where V is the ratio of visibility at frequency f to the maximum visibility at frequency 541 (I. G. Priest, "Phys. Rev.," XI., p. 498, June, 1918) (see Fig. 1). This result refers, however, to the retinal layer itself, after allowance has been made for the selective absorption of the yellow pigment and other media overlying it, and also it refers to light of equal power throughout the spectrum. Owing, however, to the presence of the yellow pigment and the other absorbing media through which the light reaches the retina, the curve of visibility no longer remains quite symmetrical when we are dealing with the natural eye, the luminosity at the blue end of the spectrum being a little depressed by their selective absorption. Moreover, average noonday sunlight at the earth's surface does not possess equal power throughout the spectrum, the intensity at the blue violet end varying for the same time of day about 30 to 40 per cent. owing to changes of atmospheric conditions (see I. G. Priest,

"Phys. Rev." II., p. 502, June, 1918).¹ Nevertheless, it remains substantially true that the relative luminosities throughout the spectrum of average daylight can be fairly represented by a symmetrical curve rather like a round-topped spurwheel tooth in shape with its maximum at wave-length 555 $\mu\mu$ in the green. Further, it remains fairly true for many other sources of white light which give a continuous spectrum (open arc, tungsten filament lamps, etc.) if we ignore the invisible ultra-violet region, except that the position of the maximum is somewhat shifted towards the red in these cases.

Turning now to the photographic aspect of the subject, let me first remind you that colour-sensitive plates are required for two very different classes of work.

In the one the records are obtained through filters (usually three), each of which allows only a sharply defined section of the spectrum to operate, the final object being to imitate the actual colours of the original by the aid of combinations of coloured pigments or stained

Fig. 2.

films. In the other class of work the aim is to procure a faithful record of the tone values of all colours in monochrome.

In the former class of photography our theoretical needs would be best satisfied by a panchromatic plate which accurately recorded the relative powers of the coloured lights acting. One which is equally sensitive to all visible parts of the spectrum of average daylight would approximate closely to this ideal. In practice, owing to the lack of transparency of all blue and green dyes (used as filters), the greater sensitiveness to blue and violet of even the best panchromatic plates is an advantage rather than otherwise. For the latter purpose, however, we should desire a panchromatic plate which required no correcting filter to enable it to record the relative luminosities of all colours as seen by the eye. Such a plate would have to possess a very strong maximum of sensitiveness in the green,

¹ See Fig. 2. The interesting series of curves reproduced here with are borrowed from Priest's paper, and bring out clearly the remarkable changes in the spectrum of daylight brought about by varying atmospheric conditions. In each case the ordinates are referred to the prevailing intensity at or near the D lines λ 589 taken as standard = 100.

falling off steadily on either side, in accordance with the luminosity curve we have already considered, towards the blue and red ends of the spectrum of average daylight. At present it is not possible to produce a plate of this kind, and we are therefore compelled to use correcting filters to hold back the blue and, to a lesser degree, the red, in order to attain our object. Unfortunately, it has become the practice to advertise colour-sensitive plates in very extravagant terms, and it is to be feared that many users of them are under the impression that one or other brand of plate of this class will give correct colour values in monochrome without the use of a filter, or at most with a pale yellow filter. In actual fact, manufacturers have not yet attained uniform sensitiveness to the whole visible spectrum of daylight, and we have already seen how much more colour-sensitive than this they must be to meet the requirements of correct monochrome rendering of all colours.

In working out practically the characteristics required in a correcting filter for the best monochrome renderings of colour, it was deemed undesirable to employ daylight owing to its uncertainty in colour from hour to hour and day to day; I therefore turned for assistance to the older data published by Sir William Abney on the luminosity of the spectrum of open arc light.

Sir William Abney made several very elaborate series of measurements of the relative luminosities of the different regions of the spectrum, using, as the source of white light, the crater of the positive pole of the open arc between pure carbon poles. The difference between this and summer daylight is, of course, appreciable, but is, I think, not sufficient to introduce any error in arriving at the quality of the correcting filter required for any given plate; for if we can work out the exact character of filter required to render correctly the relative luminosities prevailing in the arc-light spectrum, the same filter should also respond accurately to the relative luminosities in any other white-light continuous spectrum, including daylight, except at the far violet and ultra-violet end, which, however, it is best to cut out altogether in every correcting filter. I have therefore made use in what follows of results given or referred to in Abney's book, "Researches in Colour Vision." Abney's measurements all refer to the luminosities of narrow sections of the spectrum which were isolated by means of a slit of constant width = 1-25th inch (about half the interval between two of his scale numbers) caused to pass along it, and since it was a prismatic and not a normal spectrum we must make the necessary allowance for this fact.²

F. F. RENWICK.

(To be continued.)

² Abney gives on page 246 of his book several curves and a table relating to the luminosities of a normal spectrum, but no explanation of the method by which these were derived from his observations. From a passage in one of his original papers (*Phil. Trans. Roy. Soc.*, 1886, p. 456) it appears, however, that he multiplied the observed luminosity values by factors inversely proportional to the 2nd or 3rd power of the wave-length to arrive at what he calls "a very approximate curve" for a normal spectrum, but no further details are given.

EXAMINATION QUESTIONS IN PHOTOGRAPHY.

[At the City and Guilds examinations held last month, candidates presented themselves only in Grade I. of Pure Photography and of Photo-Mechanical Processes. We print below the questions set in this grade of examination in Section A, Pure Photography, and have appended to each question an answer such as a student in this grade might reasonably be expected to give. The questions and answers set in Grade I. of Photo-Mechanical Processes will appear in a subsequent issue.—EDS. "B.J."]

PHOTOGRAPHY.

GRADE I.

1. Describe any form of view-meter. State how it can be made to give accurate results, and describe exactly how it is used. (40 marks.)

A very simple form of view-meter, and one which is accurate for subjects at a reasonable distance from the camera, consists of a wire frame and a sight in the form of a small hole or an upright rod

placed centrally behind the frame at a distance which should be the focal length of the lens if the frame is the same size as the plate. If the sight is fixed on the back of the camera and the wire frame on the front, the finder will automatically adjust itself to allow for the slight extension of the camera beyond the focal length of the lens. The only error, apart from error of use, will then be that due to the difference of view-point between the finder and the lens. This will be very small in the case of ordinary views, but may be appreciable in the case of near objects. By making the frame, say, half the dimensions of the plate, the distance between the frame and the

sight may likewise be halved, and the finder thus made more compact; also the finder may be provided with a base bar marked so as to allow it to be used with lenses of different focal lengths on a given size of plate. For example, if the wire frame is half the dimensions of the plate, the bar of the finder will be marked with distances such as 3, 4, 5 ins. (from one end or the other) for use with lenses of 6, 8, and 10 ins. focal length.

2. Under what circumstances is a rising front to the camera needed (a) in landscape work? (b) in portraiture? What is the effect of using it? (30.)

(a) In landscape work the rising front is used in order to avoid tilting the camera when it is necessary to include tall parts of the subject in the photograph or to cut off a great expanse of foreground. Apart from the effect of bringing within the space of the plate objects which otherwise would be cut off by the upper edge of the photograph (lower edge of the plate when in the camera), the only other effect of using the rising front may be want of definition in the negative in the upper part of the subject if the lens has not sufficient covering power. (b) In portraiture there is very seldom any occasion to use the rising front, since usually the whole camera can be raised or lowered within the limits required for different classes of portrait in the studio. Also with an ordinary portrait lens there is not enough margin of covering power to allow of the lens being displaced from a central position in respect to the plate without loss of definition being evident.

3. If a half-plate camera gives a maximum distance of 12 ins. from back to front, and it is desired to photograph a small object so that the picture of it is three times the diameter of the object, what is the maximum focal length of the lens that will serve? Explain clearly how you arrive at your result. (30.)

In focussing the sharp image of an object so that the image is n times the linear dimension of the original, the distance from the lens to the image is n times the focal length of the lens plus one focal length. Therefore in the given case there will require to be four focal lengths within the camera extension. As this latter is 12 ins., the maximum focal length of lens which can be used is 3 ins.

4. What is the composition of the film of an ordinary gelatine dry-plate, and of an orthochromatic plate? (50.)

The coating on the glass of a dry-plate consists first of any substratum which may be applied in order to secure the adhesion of the emulsion film during development and subsequent operations. The emulsion film itself consists of gelatine containing in a finely divided state the silver compounds which are the sensitive components of the emulsion. In an ordinary dry-plate the chief compound is silver bromide, with sometimes a small proportion of silver iodide. In the case of an orthochromatic plate these compounds are incorporated with a minute quantity of dye added to the emulsion in order to render it more sensitive to green and red light. In the case of the so-called non-screen plates the emulsion film may be further dyed as a whole with yellow dye to serve the purpose of a light-filter.

5. Mention three developers, and describe how they differ from each other in their action. (30)

Taking as the three developers, pyro (pyrogallol acid), amidol, and hydroquinone, these differ as regards the substances to be used with them in order to make them practicable developers, as regards staining of the image or the film, and as regards facility of giving contrast, and they differ also in keeping qualities.

Pyro is best used with carbonate of soda as the alkali or accelerator; amidol forms a developer simply when mixed in solution with sulphite; while hydroquinone can be satisfactorily used with either carbonate of soda or caustic soda (or caustic potash) as the alkali.

Of the three, pyro produces an image which is more largely formed of stain than that given by amidol or hydroquinone; also, it is much more liable to stain the gelatine film as a whole, and for this reason requires to be made up in solution with considerable quantity of sulphite or metabisulphite. Amidol made up with the quantity of sulphite suitable to produce its developing

powers is practically free from stain, as is also hydroquinone, except that at times it is liable, in case of prolonged action and especially at a low temperature, to give a strong yellow stain.

Pyro lends itself to giving strong or soft negatives, within a given period of development, according as more or less of it is used in the developer. A developer containing 4 grs. per ounce pyro quickly gives contrast, whilst developer containing only 1 to 2 grs. per ounce gives soft negatives in the same time of development. Amidol behaves somewhat similarly, though to a lesser extent, whilst hydroquinone, especially when used with caustic soda, tends to give negatives of great contrast.

As regards keeping qualities, pyro will keep only for a comparatively short time when made up with considerable quantity of sulphite; amidol should be used on the day it is made up; whilst hydroquinone will keep for a very much longer time than pyro.

6. Describe the difference of the treatment of P.O.P., gaslight paper, bromide paper, and platinotype paper in getting prints on them, and also any difference necessary in the storage and general care of them. (40.)

P.O.P. is printed by daylight or by strong artificial light, such as arc or mercury vapour under the negative until the picture is much darker than desired. The print is then washed in several changes of water and toned in a bath usually containing gold chloride and ammonium sulphocyanide, again washed in several changes, fixed in a hypo bath containing 2 to 3 ozs. of hypo per 20 ozs. of water, and finally well washed.

Gaslight and bromide papers, when exposed under the negative, give an invisible image, which is developed. Gaslight paper may be printed by weak daylight or strong artificial light, and can be developed in weak light, such as that of a room away from the window, and preferably in the shadow of a screen. Bromide paper (much more rapid) is printed by any ordinary artificial light. Both classes of paper are developed with non-staining developers, such as metol-hydroquinone, chiefly used for gaslight, and amidol, largely used for bromide. They are fixed in hypo solution and well washed.

Platinotype paper, when printed behind a negative, gives a semi-visible image of a greyish-blue colour on the yellow ground of the paper. Printing can be done by daylight, or, if by artificial light, best by mercury vapour. The print is "developed" on a bath of potassium oxalate, where the picture appears at once and is fully developed in a minute or two, and is then "fixed" by passing it in succession through three baths of weak hydrochloric acid, finally washing it in water for a short time.

Platinotype paper requires to be kept perfectly dry in a calcium chloride tube; the other papers, and particularly P.O.P., need to be kept reasonably dry and cool if they are to retain their qualities without deterioration for any great length of time.

7. Give the details of any method of lighting a model for portraiture, and describe the result of the method that you select. (30.)

Assuming that the source of light is an ordinary window, the first step would be to block out all light up to a height of at least 4 ft. by means of a dark curtain. If the light were very strong, the upper part should be covered with butter-muslin to diffuse it a little. A dark background is placed close up to one edge of the window frame, and the model placed in front of it at such a distance that the light comes more or less from behind the sitter. The head is now turned until the profile is illuminated almost as a line, while a little light comes across and gives a soft high-light on the cheek nearest the camera. A white reflector is placed so as to give a slight general illumination to the same side of the face, but should not cause any pronounced high-lights. The result would be a so-called "Rembrandt" portrait.

8. What are the following substances used for in photography: Mercuric chloride, sodium sulphite, hydroquinone, potassium ferricyanide, ferrous oxalate. (35.)

Mercuric chloride is chiefly used for intensification of negatives, a solution of it forming the bleaching bath, on removal from which negatives are darkened (intensified) by other solutions. It can also be used in making the mercuric iodide intensifier.

Sodium sulphite is chiefly used as a preservative of developers in

solution. It is also used in compounding hardening-fixing baths, which are composed of sulphite, hypo, and alum.

Hydroquinone is used as a developer, often in admixture with metol.

Potassium ferricyanide is used in making Farmer's reducer (mixture of ferricyanide and hypo) and in compounding the bleach for sulphide toning (mixture of ferricyanide and bromide). It is also used in making the sensitiser for ferro-prussiate paper (mixture of ferricyanide and ferrie ammonium citrate).

Ferrous oxalate was formerly largely used as a developer for bromide papers, being usually compounded by mixing solutions of potassium oxalate and ferrous sulphate in suitable proportions.

9. Suppose that in adjusting the camera to photograph a bright landscape a small hole through the front of the camera is uncovered, what will be the effect on the resulting negative? (25.)

The effect will be different, according as the hole is of fair size, such as anything over an eighth of an inch in diameter, or simply of size such as a pinhole. In the former case the effect will chiefly be to fog the plate as a whole to a greater or lesser extent. If the whole is simply a pinhole and if the camera is being presented to a very brightly lighted scene a faint image, formed by the pinhole, may be produced on the plate. If the surface containing the hole is parallel to the plate this pinhole image will probably not be separately distinguishable from that formed by the lens, but if the hole is in a part of the camera at an angle a separate faint image (of a more or less different subject) may be formed. If the camera, with the hole uncovered but with the lens covered, be carried about so that the front is turned in different directions towards the sun or a bright sky the result will be to form a series of dark bands curving in all directions on the negative.

10. Why is the image on the ground glass upside down? Is it always so? (30.)

Since all image-forming rays proceeding from different parts of the subject photographed pass through the lens without alteration of direction other than that due to the lens acting like a prism, it follows that rays emanating from the highest parts of the subject arrive at the lowest part of the focussing screen, and those from the lower part at the upper portion of the focussing screen. This is always the case, except when an erect image on the focussing screen is produced by the use of a right-angle prism on the front of the lens, as when photographing a drawing or plan made horizontally or when a mirror is used inside the camera, as in the reflex camera.

11. Describe what takes place when a plate is fixed. Why is it desirable to leave a plate in the fixing bath longer than may appear to be necessary? (35.)

In fixing a plate, the silver bromide contained in the emulsion film is converted by the hypo into a compound of hypo and silver which is soluble in water.

The probable reason for fixing for a longer time than required for the disappearance of the white emulsion is that there are several compounds of silver and hypo, and of them the one containing a relatively small proportion of hypo is very slightly soluble in water. Therefore if the fixing of the plate is stopped at the stage when this compound still exists in the film, the negative may be found to retain the insoluble silver compound when afterwards washed. Moreover, this compound is one which is very readily decomposed, giving rise to brownish stain.

12. What method of intensification do you generally employ?

Why does this method of intensification render the negative more dense? (40.)

The method usually employed is to bleach the negative in a solution of mercury bichloride (mercuric chloride). The solution is made by dissolving about 1 oz. of the bichloride in 20 ozs. of water. The negative is bleached through to the back and is then well washed for at least half an-hour, and then placed in a dish and a weak solution of ammonia flowed over.

The negative becomes denser owing to the fact that on bleaching in the mercury solution the silver image is converted into a compound consisting of mercurous chloride (calomel) and silver chloride. On treating with ammonia the mercurous chloride is converted into a very dark-coloured compound, in which some of the ammonia has combined with the mercurous chloride.

VERTICAL PHOTOGRAPHS OF SMALL ARTICLES.

In the course of a series of contributions on commercial photography to our Philadelphia contemporary, the "Bulletin of Photography," Mr. L. G. Rose describes the arrangement of vertical camera and semi-transparent easel employed for the photographing of such articles as small parts of a machine where it is required to obtain a print showing the articles against a white background, but without the labour of blocking-out on the negative. In order to dispense with this blocking-out, and at the same time to obtain more relief effect and better general illumination, owing to the removal of cast shadows, the goods are laid upon a ground-glass surface, below which are arranged a number of electric lamps. In the drawing the positions of the lamps within the enclosed space below the ground glass are denoted by $\times \times \times$. The series of electric lights is placed around the lower edge of the compartment, and reflectors shade the bulbs in such a way that the light is thrown on the white floor of the lower compartment, and is reflected up

through the ground-glass. The lights are turned on for a short time—say, for about 30 seconds—when they are switched off and the exposure carried on as usual. The light passing up through the ground-glass gives more roundness to the articles and an absolutely white background, providing too much exposure is not given with the lights on; over-exposure, of course, flattening it down to a gray tone. This method is used in the larger studios a great deal, as it does away with a lot of work and blocking, and at the same time gives a much nicer effect. If it can be afforded, an opal glass instead of the ground-glass is exceedingly fine. In such work as this, where the lens is faced by a comparatively strong light, an ordinary unbacked plate must not be used. Mr. Rose finds that film is quite satisfactory, or that a plate of the double-coated type, such as 's made in America by several plate manufacturers (Seed, Cramer, and Hammer), is excellent.

SULPHIDE TONING MODIFICATIONS.

(From "Rajar Trade Notes.")

SOME years ago in our "Trade Notes" we suggested a method of obtaining by the sulphide bath sepia tones which were colder than those usually produced on bromide and gaslight papers. The results having proved so satisfactory in our own work we are anxious that our new business friends should give their attention to the method. The only difference in procedure to the ordinary bleach and sulphiding is to first of all to place the black prints in a solution of sodium or ammonium sulphide, wash, bleach, and sulphide as usual.

For good sepia tones, without any trace of yellow, on gaslight prints this method is ideal. We also find that it produces very fine tones on the new "Rajo" paper, the colour being quite distinctive.

The fixed and washed prints are immersed in the following solution for five minutes:—

Liquid ammonia sulphide	1 oz.
Water	40 oz.

or in sodium sulphide 1 oz., water 40 ozs. Very little change takes place. In this bath a portion of the silver will have been converted into sulphide. The prints should be well washed and bleached in the usual manner, but it will be found that the image will not bleach out so completely as usual. When bleached and washed, the prints are placed in the sulphide bath, and washed as usual.

We prefer the ammonium sulphide in preference to the sodium salt, owing to its being more stable and not liable to erratic action.

Another method of securing fine tones is to bleach the prints in the usual ferricyanide-bromide solution and wash well. By now putting the prints into a weak developer (Amidol or M. Q. diluted with about five times its bulk of water) the black image reappears and gradually gains in strength. By carrying the development at this stage to a greater or lesser extent, tones from warm brown to brown black can be obtained. The prints are then rinsed, placed in the usual sulphide solution, and washed. The principle here is the blending of a black silver image with the usual sulphide-toned image; hence the variety of tones obtainable by controlling the degree to which the prints are developed after bleaching.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, May 26 to 31:—

- SENSITIZED PAPER.—No. 13,314. Photographic sensitized paper. D. Blount and A. Payne.
- PLATE-CARRIERS.—No. 13,239. Plate-carriers for photographic dark-slides. W. E. Eldridge.
- OPTICAL LANTERNS.—No. 13,212. Optical lantern arrangement. R. V. Pellerey.
- CINEMATOGRAPHY.—No. 13,847. Cinematograph projectors. J. B. Barton.
- CINEMATOGRAPHY.—No. 13,848. Cinematograph cameras. J. B. Barton.
- CINEMATOGRAPHY.—No. 13,280. Separate leaf cinematographs. W. R. Booth and H. W. Hooper.
- CINEMATOGRAPHY.—No. 13,432. Cinematographic apparatus, and operation thereof. W. S. Fitch.
- CINEMATOGRAPHY.—No. 13,294. Cinematograph picture projection. J. E. Noake.
- CINEMATOGRAPHY.—No. 13,250. Taking, printing and projecting animated pictures in natural colours. W. H. Speer.
- CINEMATOGRAPHY.—No. 13,847. Cinematograph projectors. Sir O. Stoll.
- CINEMATOGRAPHY.—No. 13,848. Cinematograph cameras. Sir O. Stoll.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6s. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

FOCAL-PLANE ROLL-FILM CAMERAS.—No. 125,615 (Sept. 12, 1916). The invention relates to photographic cameras fitted with roller-blind shutters and roll-film carriers in which the setting of the shutter and moving forward of the film after an exposure is effected simultaneously so that after each exposure one operation only is necessary before again exposing the film.

In such cameras the camera body is usually fitted with a roller-blind shutter, preferably self-capping, a roll-carrier removable and replaceable for removing one film and inserting another, and mechanism or gearing which by the turning of a single handle, lever or knob will move forward the film the desired

distance for the next picture and simultaneously re-wind or set the roller-blind for the next exposure.

The invention consists in the combination of winding and setting gearing and a lever to arrest or control the movement of the setting handle, in the provision therein of a registering drum geared to the winding lever to indicate the number of film spaces which have been exposed, and in the particular construction of mechanism hereinafter described.

The roller-blind shutter is of well-known construction of the self-capping type, comprising blinds A and A' mounted on winding rollers a^1 a^2 at the bottom and spring actuated rollers a^3 and a^4 at the top, a pair of winding pinions B B', the pinion B gearing with the pinion b^1 and the pinion B' with the pinion b^2 on the ends of the rollers a^1 and a^2 , a notched disc b attached to the pinion B' between the two pinions B and B', and a spring operated pawl a to engage the notch in the disc b to retain the pinions and rollers in the set position of the blinds when the blinds are wound upon the rollers a^1 a^2 and awaiting release.

The film spool-carrier (not shown) is also of the ordinary construction with flanges at its sides to retain the film rolls in position and rollers and a plate over which the film is passed.

The rotary spigot or stub axle C by which the film roll is rotated to wind thereon the length of film which has been exposed is provided with a spindle c to which one member c^1 of a one-way clutch may be affixed and by which it is rotated, the other member d of the clutch being affixed to the winding lever D. The member d of the clutch is preferably on the face of a pinion d^1 attached to the winding lever D, though they may be separate and both affixed to the lever D to rotate with it.

The pinion d^1 gears with a train of wheels d^2 d^3 , and these in turn gear with the winding pinion B, and rotate it as the winding lever or handle D is rotated.

The winding pinion B is provided with a slot b^3 and the winding pinion B' with a pin e projecting through the slot in the pinion B. The winding pinion B' is out of contact with the pinion d^1 and is rotated by the back end of the slot b^3 when the wheel B has made part of a revolution.

The pinion d^1 is formed with the teeth only extending part way round the periphery the space without teeth allowing the pinion d^2 to rotate freely in the reverse direction when the shutter is released for an exposure. The size of the pinions d^1 , B and B' in relation to the pinions b^1 b^2 on the rollers a^1 a^2 is such that one rotation of the pinion d^1 is sufficient to set the shutter for an exposure and move forward the film the desired distance for one picture.

A stop lever or catch E subject to the action of a spring e^2 is pivoted with one end over the winding pinions B B' in the path of the pin e and the other end is provided with two projections e^1 e^3 in the path of the winding lever or handle D with which a projection e^4 on the lever D engages. The projection e^1 on the lever E has a bevelled edge e^3 and prevents the rotation of the setting lever D at any time in a reverse direction beyond its normal or zero position, and the projection e^3 comes into position to prevent the rotation of the winding handle in a forward position after the shutter is set and before it has been released for an exposure.

The shutter is held set by the pawl a which is withdrawn to release the shutter for an exposure by a lever F and sliding bolt F' or other ordinary device. The bolt F may be operated by a knob f or by a pneumatic bulb, or by a wire or other ordinary or well known device. Or a connection may be made with the winding lever D by which the release of the shutter will be effected on the completion of the winding and setting operation. For this purpose a peg or projection on the hand lever may depress a lever or catch connected with the shutter release lever.

An additional gear wheel g may be mounted on the spindle c of the film spigot C to operate, through a carrier wheel g^1 , a registering or counting drum G with numerals on its periphery to indicate the number of film spaces which have been exposed.

A second winding knob may be applied to the sleeve c^2 on film roll spigot C to draw forward the film without operating the shutter to bring the film into position for exposure and to roll the end of it up after all the sensitised length has been

CROYDON CAMERA CLUB.

AN altogether capital evening brought the formal session to a close last week, Mr. A. Dordan-Pyke (late R.A.F.) giving a lantern-lecture on "The Importance of Photography in the War," or, to put it more definitely, that section represented by the wonderful record work of the R.A.F.

Upon the lecturer devolved the task of examining some thousands of applicants for the photographic section. A few elegant ones arrived in the full splendour of top-hats, frock coats and umbrellas, radiating an atmosphere of kindly patronage to all. Army men travelled miles to inspect and enjoy these specimens, who were eventually translated to a soil which afforded a change of costume and mind. One well-remembered applicant talked so grandiloquently about his wage earning capacity of £10 weekly that he nearly arrived at his goal by sheer verbal talent. Cross-examination, however, revealed he knew nothing about photography, the alleged stipend being paid him in his alleged capacity as a receptionist. (One never knew these were male beasts, but we live and learn). Needless to say the R.A.F. declined to act as receptionist to the applicant. At the start, Grade 1 men were not accepted for the photographic section, and although this mistake was soon rectified, many a skilled photographer had drifted into other ranks and could not be traced.

As showing the rise in production of photographic chemicals during the war, the firm with whom Mr. Pyke is associated, Messrs. Johnson and Sons, supplied 100 lbs. of metal in 1905; in 1918 this had risen to 2 tons, and 5 tons of various chemicals, etc., were supplied weekly in circumstances of great difficulty. Included was a special developer for X-ray negatives, over five and a quarter million negatives being developed by its aid. A local paper ascribed this feat to the lecturer, who seems to have suffered generally from being misrepresented.

Fully seventy-five per cent. of the negatives taken, he said, were on Wratten's panchromatics, a large proportion being on an "auto-screen" panchromatic issued by the Wratten Division of Messrs. Kodak. The speed, naturally, was considerably slowed, but this was found to be of no importance, and the results were excellent.

The many superb slides shown, nearly all taken from aeroplanes, clearly indicated the knowledge gained of the goings-on of the then super-giant and now wailing Hun. The general staff invariably wanted prints in a little less than no time after the free-sittings, and, occasionally, changing boxes full of exposed plates descended to earth attached to a parachute. Vivid photographs of bombs exploding on thoughtfully selected spots, torpedoed vessels sinking, submarines executing a last submersion, gun emplacements displaced, and the like aroused the keenest interest. Some slides illustrated the exquisite defining power of the Ross Xpress lens.

It should be mentioned that two young ladies accompanied Mr. Pyke, and introduced a refining element almost unknown in the club, if rare "ladies' nights" be excepted. He made it quite clear that the unexpected pleasure was entirely due to their intense interest in the lecture. At the suggestion of the "office boy" a most cordial vote of thanks was accorded the trio.

In the secretary's boldest texting, the club's notice board contains the following disturbing announcement:—

ORDER TEA TICKETS BEFORE 16TH JUNE, OR STARVE.

Presumably this refers to the Affiliation outing up the Wandle which is now hardly at its best, but is still navigable for tadpoles of spare habit. The route fairly abounds with improbabilities for picture making.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

THE eighth meeting of the session took place on Monday, June 2, Mr. E. D. Young in the chair. The chairman introduced Mr. Robert Burns, A.R.S.A., who had come to give the society a further talk on pictorial composition. Mr. Burns referred briefly to some of his former remarks on the subject, and produced a number of photogravure reproductions of paintings by Sargent. These he placed one by one before the meeting, and illustrated the points in the composition of each by means of a blackboard, on which he drew roughly the "bones" of the composition. By this means he showed the importance of the chief lights and shadows of each picture; and, in order further to demonstrate his meaning, he

removed or altered the position of some of the more important features, and by this alteration of the arrangement showed how easily the entire scheme could be thrown out, and consequently how important and necessary was each point in its particular place.

Sargent, the speaker explained, was, more than any other artist, akin to the photographer. His work did not depend so much on colour as on light and shade, character and likeness. A photographer should endeavour to obtain the likeness of his subject as he or she appeared under normal conditions. The friends of the subject were accustomed to see him or her under all sorts of lighting conditions; but to see the person at home under a lighting in which only a small part of the face was visible—the remainder being lost in shadow—was not a probable occurrence.

The first reproduction shown was that of the head of a man with face turned well toward the light, leaving only the right jaw and ear in shadow. This latter arrangement just prevented the face from being a mere geometrical figure. It was most important to avoid all similarity to geometrical figures in composition. The speaker reminded the meeting of his previous talk, when he had pointed out that in most cases good composition was found to be triangular; but, nevertheless, the triangle should not approach the equilateral form.

The next illustration was that of an old man, full-length, seated in a chair, with hands folded, of which the three main points were the face, the hands, and a light at the bottom of the picture slightly to the left. Mr. Burns pointed out how important was the fact that the two lower points were closer together than to the first point, and showed, by making the three equidistant, that these two then became of equal value with the head, and thus detracted from what was, of course, the proper centre of interest. A globe introduced in shadow to the right of the figure served to counteract the tendency to too straight a line in this composition. The introduction of such accessories in a photograph was discussed, and the difficulty was pointed out that such things were apt to insist more upon their presence than the photographer had thought or intended.

A skilfully-arranged group of three women was then shown. Here, it was pointed out, the heads were not equidistant, as they might easily have been, but were formed into a group of two, with the third slightly apart. The height of the heads, likewise, was not the same, but they formed a line approaching an inverted curve or modified U-shape. This line was a good one to use in such circumstances. A dog introduced at the left-hand bottom corner of the group—though perhaps not a very happy inclusion in this instance—was shown, nevertheless, to be absolutely necessary. In another group of three women, where one sat, and the others stood on either side, the same curved line of the three heads was evident; and a clever use of a sash was shown to obviate the too close repetition of the one standing figure by the other. An alternating arrangement of a light dress against a dark portion of the background, and a black hat against a light part, also gave variety. Yet another group of three gave illustration of the fact that an ostensibly accidental upright line of light in the background may assist not only in the balancing of the picture, but help to carry the main line to completion.

In an upright full length figure of a man, a walking-stick in the left hand served to balance a light in the diagonally opposite corner of the canvas; and, in another, a shadow in the lower half of the background served the purpose of shortening what would otherwise have seemed too tall a figure. A fine head being shown, the speaker paused to remark upon the skill with which this was placed upon the canvas. Mr. Young mentioned that most photographers were in the habit of placing the heads of their subjects lower in the picture than was customary among artists. Mr. Burns emphasized the necessity of avoiding anything approaching a "bull's-eye," caused by placing a head in the centre. The apparent height of a head could be greatly altered by the raising or lowering of an important object below it. An illustration of this was given.

A general discussion then took place, in which the difficulties of painted backgrounds were mentioned. It was felt that for the purposes of a background a long studio, one end of which was lost in shadow, would be a desirable one for a photographer. The meeting closed with a hearty vote of thanks to the speaker.

Commercial & Legal Intelligence.

NEW COMPANIES.

ENTWISTLE, THORPE AND CO., LTD.—This private company was registered May 28, with a capital of £2,000 in £1 shares (750 7 per cent. participating cumulative preferred). Objects: To take over the business of drawing-office material dealers, commercial photographers, photo-printers of plans and other documents, and photo-engravers, carried on by H. Entwistle and W. H. Thorpe, at 35, Great Peter Street, S.W. Permanent directors, H. Entwistle, 11, Redclyffe Road, Withington, Manchester, drawing-office stationer; W. H. Thorpe, 9, Harold Street, Middleton, Lancs., drawing-office stationer. Solicitors, F. Entwistle and Sons, 83-5, Long Street, Middleton.

News and Notes.

CELLULOID in sheets, rolls, and rods is in the list of articles restriction of the importation of which has been removed by the Board of Trade, after consideration of the recommendations of the Consultative Council on Imports.

THE LATE C. WELBORNE PIPER, among other bequests to relatives and friends, left the sum of £20 to the Croydon Camera Club "to do as they liked with." It is not difficult to imagine what the Croydon Camera Club will try to do with the money.

HIS MAJESTY THE KING, during his visit to Leicester on Tuesday last, visited the lens and optical factory of Messrs. Taylor, Taylor and Hobson, where he and the Queen inspected the processes in the manufacture of lenses. Mr. William Taylor, by whom the works were shown to the King, explained the methods adopted in the highly delicate figuring of the glass surfaces.

AERIAL PRESS PHOTOGRAPHS.—On the first day of the establishment of an aeroplane series of trips between Blackpool and Manchester, Mr. F. T. Curson, "Daily Sketch" photographer, was a passenger, and although the weather conditions were unfavourable, took a number of photographs, which were reproduced in the "Daily Sketch" and the "Daily Despatch."

MR. J. A. BALDWIN, proprietor of the Sunderland and West Hartlepool Studios of Hancock and Co., and formerly of the Photographic Section, Royal Air Force, is holding an exhibition at his Sunderland Studio, 312, High Street West, from June 17 to 27, of pictures taken by him in Mesopotamia. The exhibition will consist of about 240 sepia bromide enlargements of life and scenery in Mesopotamia. Mr. Baldwin will be very pleased to send a card of invitation to anyone interested who will apply to him.

DAGUERREOTYPES ON LOAN.—Mr. William Tylar, formerly of Birmingham, and now of Victoria Road, Ferndown, Dorset, informs us that he has a collection of fine specimens of the Daguerreotype process, of quarter-plate size, and in almost all cases representing persons of standing at the time the portraits were taken. He is prepared to lend a set of ten of these Daguerreotypes to any professional photographer who is anxious to use them for a window display. The charge is 7s. 6d., plus postage, for a week's hire.

FLASHLIGHT ACCIDENT.—A photographer of Raleigh, N.C., may suffer the loss of one eye and his left hand as a result of a bottle of flashlight powder exploding in his hand while he was attempting to take a flashlight picture in one of the departments at a tobacco factory. He was working with an electrical apparatus which was used for igniting the flashlight powder. In attempting to pour some of the powder from a flask into the firing tray a short-circuit in the wiring caused a premature spark, which ignited the powder in both the tray and in the bottle.

BRITISH ASSOCIATION GEOLOGICAL PHOTOGRAPHS COMMITTEE.—The Secretary, Mr. S. H. Reynolds, The University, Bristol, writes:—Very few geological photographs have been received during the last few years for obvious reasons. The committee, however, hope that

as the war may be considered to be at an end, a good series may now be contributed. In order that they may be incorporated in the forthcoming report, photographs should be sent to the secretary not later than the end of July. It is particularly desired that copies of all published geological photographs may be received.

THE AFFILIATION OUTING.—In the capable hands of Mr. J. M. Sellors, honorary secretary of the Croydon Camera Club, very complete arrangements have been made for the summer outing of affiliated societies to Croydon on Saturday, June 21. The district to which members of the party will be introduced is that from Waddon through Beddington, Carshalton, and Carshalton Park to Wallington. Arrangements have been made for the issue of a map by which members of the party can explore the photographic attractions of this district, along the route of which they are to go as and when they please, and will encounter members of the Croydon Camera Club for their guidance and information at certain points. Ticket for tea at 6 p.m. in the Christchurch Presbyterian Hall, Wallington, is also a ticket of special permission to photograph in the ancient buildings on the route, such as the Archbishop's Palace and the Whitgift Hospital. Medals for photographs taken on the outing are offered by the Croydon Camera Club, the United Stereoscopic Society, and by an anonymous donor. Complete particulars of railway and other arrangements are contained in the circular obtainable from Mr. Sellors, 27, King Street, Covent Garden, W.C.2.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS.—At the annual general meeting, held at Blackpool on May 27, it was announced that the election of several new members has brought the total membership up to 140. Following the president's address and reports from the hon. treasurer and hon. secretary, the election of officers for the current year took place. The following officers were elected:—President, F. Kenworthy; hon. treasurer, F. Read; hon. secretary, W. H. Huish. Committee, J. P. Bramber, H. Baylis, W. P. Beck, W. T. Parker, G. Connard, C. Foley, R. H. Gresswell, H. Haugb, C. Howell, H. Melling, J. Saronie, J. W. Stott, A. Walmsley, J. Watson, and A. Winter. The address of the newly-elected secretary, Mr. Huish, is 39, Blackfriars Street, Manchester, where all communications for the Society should be sent.

The thanks of the Society were accorded to the photographers who had contributed examples of their work to the loan section of the exhibition held by the Society at Blackpool. These exhibitors were:—Messrs. Marcus Adams, J. E. Bacon and Sons, A. Basil, William Crooke, J. Donovan, F. H. Evans, W. Illingworth, Alex. Keighley, H. Lambert, R. M. Morgan, R. N. Speaight, J. B. B. Wellington, and Mr. and Mrs. Williams.

AMERICAN AERIAL PHOTOGRAPHY ASSOCIATION.—Nearly 4,000 photographers, both professionals and amateurs, were in the Photographic Branch of the Air Service during the war. An association of these has been formed and has recently sent out a plea for all men who were members of this branch to join and thus help preserve the friendships and objects of the Aerial Photographic Service.

Enlisted men at the Army School of Aerial Photography, at Rochester, took the initiative in this movement and formed the U.S. Army Aerial Photographers' Association last December. Honorary members include Lieut.-Col. John S. Sullivan, Major James Barnes, Capt. M. A. MaKinney, Jr., Lieut. Wm. D. Wheeler, Capt. Harry A. Wilsdon, Lieut. Andre H. Callier, Mr. George Eastman, Mr. W. F. Folmer, and Dr. C. E. K. Mees, all names well known to the photo branch men. The president of the association is Henry Van Arsdale, Jr., 25, West Forty-fourth Street, New York City. Communications regarding membership, etc., should be sent to Carl Kattelman, secretary-treasurer, 617, H Street, N.W., Washington, D.C., or to Wickham Harter, assistant secretary-treasurer, 636, East State Street, Trenton, N.J.

It is the intention of the association to obtain a large membership so that it will be possible to issue, at intervals, a publication dealing with matters of aerial photographic interest, to hold a large reunion in Rochester this summer, to conduct local reunions, furnish membership pins, and generally keep aerial photographic interest alive.

Correspondence.

SOUTH AFRICA AND ASSISTANTS.

To the Editors.

Gentlemen,—At this juncture I think a word of advice to my fellow-assistants will be appreciated. I came out here about 14 years ago, and have seen the growth of photography during that time. My main purpose is to advise all assistants thinking of coming to South Africa to be careful just at present, and to see that a proper wage is paid for their services. There is a demand for good men here, but they should not make the mistake that I did in accepting a billet for a number of years at a ridiculous salary. At present living is extremely high, clothing and general necessities of life are so highly priced that only those out here know what amount is required. A good all-round assistant who knows his work should not come out for less than £40 per month; this may seem a lot to some, but it is sufficient, and will enable one to save a little, not much. The climate is good, except in Durban or Bloemfontein, where it is frightfully hot in summer. Plenty of light clothing should be brought. Above all, the assistant who thinks of coming out here should be sure that his health will stand the climate, or he will be paying the doctor 10s. each visit. I send this advice because the agent who sent me out told me I could live on £5 per month and save heaps. I was sorely disappointed, but having signed the agreement I had no other choice. So, comrades, take care. We want good men who can earn good money.—Your well-meaning

COMRADE.

Johannesburg, May 1.

ASSISTANTS' WAGES.

To the Editors.

Gentlemen,—I cannot quite agree with the remarks of your correspondent "An Assistant," writing in the "B.J." of May 30 p. 303. In the first place, I doubt very much if there are any employers about at present who would expect to engage a "thoroughly competent and capable man" for anything like £2 per week, unless it be for one whom he terms "war product." In the second place, I doubt if actual promises were made by any employers to keep places open for patriotic assistants, unless in a few rare and exceptional cases. A really capable and competent operator-retoucher can easily demand and get £5 per week and upwards. If your correspondent happens to be one of those unfortunate "two pounds a week," then by all means let him get in touch with me. If he is the right man I may be able to give him a useful hint or two.—Yours faithfully,

AN EMPLOYER.

LANCASHIRE MASTER PHOTOGRAPHERS' EXHIBITION AT BLACKPOOL.

To the Editors.

Gentlemen,—On receiving my "B.J." last Friday I was rather anxious to see what was said in reference to the above, but I was not surprised to find that the remarks were about equal to the exhibition or the "Quiet Little Show" as it is termed. When I saw the exhibits in the small room I asked for the other part of the exhibition, but I was told it began and ended there.

Of course that accounted for no catalogues—it wasn't worth it I imagined how it would have looked if there had been no mounts, frames or glass as intended at one period of the arrangements.

Amongst the master photographers' exhibits I was pleased to see some very fine work, and well worthy of copy in pose and execution; but for the gem of this section I should be a long way from agreeing with the writer of last Friday's article. On learning that the exhibits were to be judged by the secretary and members, I looked for the result in last week's Journal, but I did not see any mention of it. I have also made several enquiries, but I am no nearer knowing the result of voting.

Perhaps the secretary and committee will provide an exhibition next year that will be worthy of the name "Lancashire Master Photographers," and show what the men of Lancashire can do! Yours faithfully,

"HOPEFUL."

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

K. K.—You can get all particulars of frame-making tools from Messrs. Melnish, Ltd., Fetter Lane, E.C. We are sorry we have not their catalogue here, but in any case prices in it would probably now be out of date. About your nearest firm, and the one nearest to you, is Messrs. Bennett and Jennison, Ltd., Wellington Works, Weelsby-street, Grimsby. We are sorry we have no information as to wages of picture-frame makers.

C. T.—It would probably cost you several times what the lens is worth, and considerably more than the price of a portrait lens working to focus, to have new correcting glasses supplied. You might ask a firm such as Messrs. R. and J. Beck, Ltd., 56, Cornhill, London, E.C., to quote you a price, but if we were you we should sell the lens and buy one of the ordinary type. These old non-achromatic portrait lenses give very good results, but many like yourself, do not like to be bothered with the adjustment of focus.

T. J. If you copy half tone illustrations on process plates and make negatives as good as can be made on these latter, lantern-slides from them are bound to show considerable structure when magnified on the screen. One way of getting over this is to make the negative on a rapid portrait plate. Unfortunately, you then lose a good deal of vigour, but probably you can get sufficient for your purpose by printing from the negatives on gaslight lantern plates, using a developer like hydroquinone made up with caustic soda, which gives contrast.

A. G.—1. Alcohol, from any pharmaceutical chemist. 2. If you mean finely powdered Indian ink, it is not sold. You can either buy the sticks or liquid preparations from dealers in drawing-office materials. 3. No objection to using lead in repairs of developing tanks. 4. If you have plenty of calcium chloride, say seven or eight pounds in a tin such as an ordinary despatch case, probably three or four hours will be ample to dry the paper. But, of course, everything will depend on the dryness of the chloride.

SAFE LIGHTS—Could you please tell me what preliminary coating to use on glass before floating with gelatine and dye solution in making safe lights, as I find in using formula from the "B.J.," p. 317, that as soon as the gelatine is bone dry it peels right off the glass? What is the best gelatine to use? Have tried a fixed-out dry-plate, with the same results.—T. N.

You can give a preliminary coat of albumen or gum, but your difficulty is probably due to the use of too hard a gelatine. Use a soft gelatine, as supplied for cooking purposes, and avoid rapid drying.

A. J. W.—The button cameras came largely from America, and therefore, owing to prohibition of imports, are scarce. Your best chance of buying one is from the second-hand dealers, such as those whose advertisements you will see in our pages. As regards licence, the practice of the police authorities, who regulate the users of such apparatus, varies a good deal. In some places they make the man take out a hawkers licence, at the cost, we

think, of 5s., but in other places there is no restriction. Any head police office in the district where you intend working would give you the information.

G. E. R.—We think your difficulty lies in the handling of the prints. So long as the developer is reasonably fresh you may be certain that it is not the cause of the stain. Our advice to you is to use invariably an acid fixing bath and a print paddle—the latter any light strip of wood with rounded edges. If you immerse each print as it comes from the developer well under the surface of the fixer, and keep it there for a few seconds by means of the paddle, we think you will find you will get no more stains. As good a formula as any for the acid fixer is 4 to 6 ozs. of hypo and $\frac{1}{2}$ to 1 oz. of potass. metabisulphite in 20 ozs. of water.

SALONICA.—A process such as that of Mr. John Sterry, published some years ago, is perhaps what you are seeking. The negatives are immersed for thirty minutes in:—Potass. carbonate, saturated solution, 2 ozs.; glycerine, 1 oz.; formaline, 1 oz.; tap-water, 50 ozs. All by measure. Let the plates soak in this for about half an hour, and then put them aside to dry slowly; it will take from six to twelve hours. If then a narrow edging is cut off all round the negatives with a sharp knife the film within this edging can be raised at one corner, and then steadily pulled off. If preserved between flat cards or in the leaves of a book the negatives can be kept indefinitely.

S. H.—Books on colour photography are very few and not very good. About the only one which is worth while to recommend to you is "Photography in Natural Colours," by Dr. König (Hiffe, price 3s. 5d.), but it deals with the later processes, and next to nothing of Autochrome or Paget. On these latter the only literature, apart from what has appeared in the photographic journals, is the books and leaflets which are obtainable from Mr. T. K. Grant, 89, Great Russell Street, W.C. 1, and from the Paget Company, Watford. Practically the best notes and papers on the processes are in the journals. There is a little book on "Colouring Photographs and Lantern Slides," by R. Penlake, price 1s. 8d., from Messrs. Hiffe, 20, Tudor Street, E.C.

S. W.—The arrangement for lighting shown on your sketch should answer very well. A French grey would be suitable for the walls. You can of course have a darker tint if you provide a good sized reflector. We have found 200 or 250 c.p. sufficient for a 1/1pl. enlarger, unless the negatives are very dense. Even then a long exposure will give you good results, while for thin and medium densities the light is ample. If you can dispense with a condenser and use reflected light you will want about four 500 c.p. lamps. Enclosed area are best for this. Using £4.5 and Ilford Zenith or Imperial Flashlight plates your exposures with six 1,000 c.p. lamps should be from 1 to 3 seconds, according to distance between sitter and light.

P. L. M.—Various dodges have been used to dull the surface of metal articles so as to avoid the occurrence of reflections. For example, dabbing with putty or depositing a thin layer of magnesium oxide by burning magnesium ribbon, or spraying with a neutral colour with an air-brush, or in the case of a vase putting ice in water contained in it so as to give a deposition of diox on the outside. But none of these methods are so efficient as placing the article to be photographed in a miniature studio entirely enclosed with muslin, except at one part, where a high-power lamp can be put, an order to give the necessary relief of lighting. The little manual "Commercial Photography," supplied by our publishers, price 1s. 2d. post free, gives detailed instruction.

FIXING-HARDENING.—Will you kindly let me know the best hypo bath to prevent my plates frilling? My dark-room is very small and the incessant heat softens the film. I tried adding alum to the hypo, but got a milky coating over the negatives which was very difficult to remove. I want a bath that will fix and harden them in the one operation.—A. J.

Addition of alum alone to the hypo bath is very bad practice since it gives a bath which not only is milky but will readily cause stains to develop afterwards in the negatives. A suitable hardening bath consists of 20 ozs. of saturated solution of alum, 4 to 7 ozs. of saturated solution of sodium sulphite, and from 20 to 28 ozs. of hypo solution containing 1 part of hypo dissolved in 5 parts of water.

COPYING LENS.—Will you kindly let me know if you can copy photographs on a half-plate with a 5-in. focus wide-angle lens, which I purchased some time ago as a half-plate wide-angle lens? I have only the ordinary double extension camera and I could not use a large focus lens with such extension.—R. A.

Provided that the 5-in. lens covers a half-plate in the ordinary way satisfactorily (it should do so) there is no objection to its use for copying, except that it becomes rather slow. If you are copying same size (extension of camera 10-in.) the f/16 marked on your lens becomes f/32, and the same applies to every other stop and still more when you are copying-enlarging. If your camera extension is 20 in., the 5-in. lens would allow you to enlarge when copying to about 3 diameters.

C. W. A.—If your business is carried on out of doors, as we suppose, by canvassing people or establishing yourself on a pitch and waiting for people to come to you, then we should say you do not come within the scope of the so-called Retail Business Licensing Order, the office of which for your district is Iddesleigh Mansions, London, S.W.1. But in many districts the police require a photographer carrying on a business of this kind to take out a hawkers' license at the cost of, we think, 5s. 2. There are many restrictions on photography, for example in the parks, County Council gardens, Hampton Court grounds, etc. If you buy a copy of the Wellcome Exposure Record, which you can get at any photographic dealers for 1s. you will find full particulars there where to apply for permission in places where it is needed.

C. P. L.—1. The camera we referred to was the "Sibyl," of Messrs. Newman and Guardia. The baseboard covers the lens; the focussing movement is operated by a finger lever on the front of the baseboard; though the lens front does not come automatically into working position when the camera is opened, it is almost automatic, and the mechanism is much less liable to derangement than the spring-operated automatic cameras which one has had but which have not been successful on the market. 2. We do not know of any special description of easel for colouring photographs. Professional colourists usually use the ordinary artists' easel as supplied by Messrs. Winsor and Newton, 37-40, Rathbone Place, Oxford Street, W.1. Amateur colourists have a very good easel supplied by Messrs. James A. Sinclair and Co., Ltd., 54, Haymarket, S.W.1.

Line Advertisements.

Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.

(No reduction for a series.)

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add ... 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed Adv'ts should reach the Publishers on Monday morning.
The insertion of an Advertisement in any definite issue cannot be guaranteed.

SUMMARY.

The interior decoration of the studio has hitherto been done on somewhat cautious lines; in an Ex Cathedra paragraph we detail an example of rather daring treatment which has proved attractive without detriment to the work. (P. 345.)

A lens chat forms the "Practicus" feature this week. The writer without specifying various makes deals with the general qualities of such lenses as are likely to find their way into the hands of the portraitist. (P. 349.)

The questions set at the recent examination of the City of London and Guilds Institute in the ordinary grade, Section B, of photo-mechanical processes are given with suggested answers on page 353.

The concluding portion of the paper by Mr. F. F. Renwick on colour values in monochrome will be found on page 351.

The second of a series of articles on stereoscopic photography deals mainly with portraiture, a branch which we fear has never received the attention which it deserves. (P. 346.)

An important communication as to the necessity for licences for new photographic businesses, giving a list of branches for which no licence is required, appears on page 357.

The present instalment of "Camera Movements" gives a fully detailed explanation, with diagrams, of the function of the rising front and swing back, with hints on the use of the spirit level. (P. 348.)

A hint useful to all who have to copy matt-surfaced prints and are troubled with "graininess" will be found on page 355.

Under the heading of "Patent News" we give abstracts of specifications of a folding pocket camera and an electric retouching device, together with a list of recent applications. (P. 356.)

Modifications of the Coal, Gas, and Electricity Rationing Order which will be in force for some considerable time are detailed on page 357.

Letters from an assistant and from an employer on the wages question, a note on stereoscopic separation, and holiday closing in Londonderry will be found in the correspondence columns on page 358.

Hot weather troubles, studio illumination, backing plates, and tank development are, with other subjects, dealt with in "Answers to Correspondents." (P. 359.)

The desirability of avoiding the use of misleading descriptions of printing processes, frames, and the like as a stimulus to a better class of business is pointed out on page 345.

A suggestion for producing advertising specialities and souvenirs might perhaps be carried out by the aid of carbon or transfer-type by the ordinary photographer. (P. 355.)

EX CATHEDRA.

The Real and the Imitation. In nearly every branch of commerce we find imitations masquerading under names as closely approximating to that of the genuine thing as the law will allow. We have rolled gold, which is the thinnest possible film of genuine metal which can be made by mechanical means, "Walnut finish" furniture, which is white wood stained brown, and others too numerous to mention. In photography we find the same idea not carried so far, but sufficient to mislead those who are not acquainted with the technics of photography, especially as regards printing processes. The word "platinotype" is very loosely employed; for instance, we see "platinotype panels" or "platinotype sketches" which have no more platinum in them than there is in a piece of newspaper. In the same way we have "carbon" papers of various kinds, which are as far removed from genuine carbon prints as it is possible to be. Gilt frames are innocent of gold, the colour being obtained by lacquering white metal, but this is not known to the public, who would often prefer "English Gold" if the difference were clearly pointed out. With prints the same result would in many cases be secured, that is to say, people would be glad to have real platinum and carbon for the sake of assured permanency. There are many other instances which could be given, but we will content ourselves with mentioning one only—the practice of calling coloured photographs oil paintings or water-colours. This is not, perhaps, so extensively practised as it was some years ago, but it is to be discouraged, and the use of the term "finished in oil or water-colour" should in every case be used.

Colour and Aspect. When decorating a studio the effect of the aspect upon the colour used for the walls is very often overlooked, the colour being chosen either according to the personal predilections of the proprietor or for some more or less imaginary photographic value. The trained art decorator works on a different plan, and usually endeavours to brighten up a room with a northern aspect, and to produce a cooler or more subdued effect on one facing south or west. This idea is rarely followed out in studio decoration, for in this we usually find that cool colours are employed, while the room itself has, in the great majority of cases, a northern aspect. There is really no good reason for this, and we think that a little more daring might be shown in the choice of colours. We have recently visited a studio with a northern aspect, the walls of which are painted a deep orange chrome, relieved by a skirting and frieze of dark, almost indigo, blue, and found after recovery from the first shock to our conventional ideas that the combination was quite pleasing and free from any garish effect. It might be imagined that the effect of painting the walls with a colour which is

practically black from a photographic point of view would be to interfere seriously with the lighting, but an inspection of the work done proved that this was not so, for although the artist favoured rather strong effects, there were some quite silvery in character, and as a whole there was no difference between them and pictures made in a studio with the orthodox greyish interior. This opens out a wide range of possibilities in decoration, colours which have always been considered as tabu being apparently quite innocuous as far as the work is concerned. We have always been opposed to the very light colours which most photographers have considered to be essential, and have found a great improvement in lighting with a west-lighted studio in changing the walls from a light French grey to a rather dark greyish green, more brilliant negatives being thus secured. Our older readers may recollect that a good many years ago an "orange pea-green," whatever that may be, was strongly recommended for photographic reasons, so that the idea is not quite a novel one. But the lesson remains that we may indulge our artistic instincts in decoration to a much greater extent than we have done without bringing discredit upon our pictures. It may be worth adding that only ordinary plates were used in the orange-lined studio.

STEREOSCOPIC PHOTOGRAPHY.

III.—STEREOSCOPIC PORTRAITURE.

It is hardly sufficiently realised how valuable stereoscopic photography is in the province of portraiture. No one who has ever seen a really successful stereoscopic portrait can have failed to remark upon the almost uncanny realism of it. To the artist it is perhaps too gross a realism. It has that death-in-life or life-in-death quality

not the amateur need have no hesitation in taking up the work, and if he will do so he will be surprised and delighted at the results, as will his sitters also.

It is hardly necessary to point out that for stereoscopic portraiture twin lenses and a stereoscopic camera are practically essential. To take successive portraits in the hope that no movement will have occurred in the 30 seconds or so occupied in the changing of camera position would be futile, and the use of mirrors with a single lens would mean a reversal of the image fatal to correct portraiture. Pinhole photography is unsuitable owing to the long exposure required, and the twin-lenses arrangement seems the only way to ensure perfect results.

The surroundings and background having been appropriately arranged, the principal light should be well concentrated on the face of the sitter. A three-quarter-length will generally be the most effective portrait.

It should be known that in the case of a plain background the prints may by suitable masking be made to show a head or, indeed, any object well in front of the picture plane. To effect this the background is masked in two circles, squares, or ovals of equal size, the two being at the extreme limit of $2\frac{3}{4}$ inches apart, while the portraits themselves are only separated by $2\frac{1}{2}$ inches. This means that the head in the left picture is a little to the right of the centre of its background, and in the other a little to the left of the centre, the backgrounds being, of course, the same size and shape. The result is a portrait standing as it were solidly in space with a background well behind. If the masking is carried out the other way, bringing the head in the left-hand picture to left of centre and in the right-hand picture to the right, the portrait will recede behind the picture plane. This is always the best way of masking a landscape and generally best for a

Stereoscopic portrait of the late Washington Teasdale.

which is the bane of the wax-work show, and yet apart from that there is a preciousness about such a vivid relic of a dead or absent friend that must be recognised. How religiously we should cherish, if it existed, such a presentment of any of the "great ones gone," or, to bring it closer home, of some dear departed member of one's own family. The professional photographer never seems to have found it worth while to push this branch of his work. Perhaps he knows his public too well to venture on the enterprise of stereoscopic portraits. Whether this is so or

portrait. The effect then is that of a picture seen through a frame; occasionally, however, in portraiture, an amusing effect is procured by the opposite plan, allowing the head to look out from beyond the frame. In stereograms of such subjects as museum exhibits—a fossil or a mineralogical specimen—it is also generally best to mask so that the object is in front of the picture plane.

The chief drawback to stereoscopic portraiture is the need of a stereoscope to view the results. This objection must, of course, be admitted, but it should be pointed out here

that the knack of seeing stereoscopically without any instrument is so extremely easy to acquire that it is a great pity it is not more general. Most people can learn the way to do it after one or two trials, and then with a very little practice it becomes practically instinctive. The writer scarcely ever uses the stereoscope, and never has a moment's difficulty in combining the elements of a stereogram with the unaided eyes. It is very advantageous in mounting stereograms to be able to do this, as it precludes any possibility of mistaking the right-hand for the left-

scopic treatment almost more wonderfully, as it keeps the attention concentrated on the figure, and we really get as near an approach to an actually "speaking likeness" as mechanical means can accomplish. A good example is shown in the second illustration, in which all accessories are avoided.

There is one important point in stereoscopic portraiture—the process which goes by the name of retouching must be eschewed, unless the retoucher is particularly skilful in treating the two pictures exactly equally, and even then

Stereoscopic Portrait by Oscar Way, Colchester (slightly retouched).

hand picture. It is also convenient to be able to enjoy stereograms in a book just as well as on separate cards.

The way in which it is done is a little difficult to describe in words, but briefly it consists in fixing the eyes on an imaginary distance as though looking through the stereogram at something beyond. This involves no squinting; there is no more convergence of the eyes than in looking at any object a yard or two away. Probably the only difficulty in seeing stereograms in this way is that while looking through at the imaginary distance one naturally focuses the lens of each eye for that distance, whereas this instinctive tendency has to be resisted as we require to focus them for the stereogram while converging them for a more distant object. The art of doing this soon comes, and with a little practice one learns to combine readily pictures even as widely separated as four inches or more. If the faculty of stereoscopic vision were more widely cultivated stereoscopic portraiture would be proportionately more popular.

In stereoscopic portraiture it is tempting to introduce intricate accessories to add to the magic of the stereoscopic relief. The accompanying portrait of the late Mr. Washington Teasdale with his "geometric pen" is a good example. The photograph necessarily loses much detail in reproduction, but the original is strikingly effective in its fidelity to the intricacies of the apparatus, with its levers and cogwheels. On the other hand, pure portraiture with a plain background lends itself to stereo-

much less should be done to the negative than is usual in professional photography. The illustration, a stereogram by Mr. Oscar Way, of Colchester, is an example of the retouching of a print carried as far as is practicable for the stereoscope without sacrificing relief or losing the character of the sitter.

Retouching in portraiture generally has come to be considered necessary, largely because the public will inspect a photograph at a proximity to the eyes at which they would never think of scrutinising the painting of an artist. The lines which the retoucher so carefully eliminates in deference to public taste in the matter of wrinkles are not really the blemishes that they have come to be accounted. In them a great part of the character resides, and if they show unduly it is often that the lighting has not been judiciously arranged, or that the print is being examined from too close a point of view. Place an untouched print in a frame on the wall and view it at a reasonable distance. It will be seen at once to be immeasurably superior both as a likeness and an artistic production to the smooth, characterless wax effigies which so many photographers turn out—not perhaps to please their own taste, but simply because their public will have it so.

Now, in stereoscopic photography retouching is not very practicable, for any marks made by hand are apt to show up, in mid-air as it were, in the stereoscope, nor will it be found that even popular taste will object to the true

presentment of lines and wrinkles in a stereogram. So that in stereoscopic portraiture the photographer is happily saved by the very necessities of the process from a practice which is of doubtful advantage in portraiture in any case, and beyond that is generally carried to an extreme that to the true artist borders on the offensive. In speaking of "retouching" we are not, of course, including mere "spotting out" or the removal of mechanical defects in a negative caused by dust particles, etc.

Freckles, too, by their non-actinic colouring, are unquestionably too conspicuous on a photograph, and it is often desirable to remove this defect by working on the negative. To the elimination of such spots no objection can be raised, though possibly a certain amount of valuable time is sometimes wasted in getting rid of specks so microscopical that their presence or absence is a matter of absolutely no importance.

C. E. B.

CAMERA MOVEMENTS.

II.

THE previous article described the various possible adjustments, or movements, as they are usually termed, that a stand camera should be provided with, but it pointed out that they are seldom, if ever, all found in one camera. Probably there is scarcely a stand camera built nowadays that has not at least a rising (and falling) front and a swing-back, and these are the movements not already sufficiently explained which are most used, and they will therefore be considered first.

Supposing it be required to photograph a building, a church, for example, the camera is set up pointing towards it and levelled by means of a spirit-level. If notice has been taken of what has already been written, the front and back of the camera will be perfectly vertical. If the camera is stood up far enough away to include the whole of the church when the camera is level and the lens central, it will be noticed on the focussing screen that nearly half of the image consists of foreground, road or field, may be, and that the subject itself, the building, occupies the other half, and therefore looks insignificant. The reason for this is very simple. The camera is looking straight towards the building, and the level of the lens is about half-way up the door. As the lens level is the centre of the ground-glass, it follows that there will be as much included below the centre of the subject as above it. To photograph the church with the camera level as described from a nearer point, so as to get the image larger and with less foreground, it would be necessary to raise the whole camera opposite to the centre of the subject, which is seldom possible. However, the rising front enables the desired result to be obtained in most cases while the camera is still standing on the ground. It appears miraculous to some people that the effect of raising the lens an inch will give the same effect as raising the whole camera twenty or thirty feet perhaps, but the following explanation should make the reason clear:—

Fig. 1.

Fig. 1 represents the camera set up opposite the church at a distance that will give it a nice size on the plate, and on levelling it is found that the image includes what is between the lines AA, and the effect on the ground-glass is seen diagrammatically by the solid lines AA in Fig. 2, where the point

of the subject that is on a level with the lens is found in the centre of the ground-glass and is marked with an X. The image of the steeple is formed in the margins of the circle of light produced by the lens, but is outside the area of the ground-glass, as shown by the dotted lines. If the lens is raised the image formed by it is raised also, so that the steeple can be brought into the picture quite easily. The whole image moves, remember, so that when the lines BB are raised till they correspond with the edges of the ground-glass AA, it is obvious that as more of the image is slid into view on one edge, an exactly equal amount is slid off the ground-glass on the other. The image is there all the time. One simply slides the portion one wants of it on to the focussing screen.

A cross-front, a sliding movement from side to side, works in exactly the same way when it is required to include more of the subject on one side of the plate and less on the other, when it happens that one cannot stand opposite the middle, but, still, a perspective view is not wanted. This is especially useful in copying to adjust the image centrally on the ground-glass.

It may happen that the amount of rising front is not enough to include all of a building; for instance, where the latter is extra tall, or where it is not possible to get further away to include more of the view; or it may be that the definition at the margin of the image is not good enough to show the subject properly. In that case the proper course is to tilt the camera so that the lens points upwards. That is to say, to point the lens towards the centre of the subject required on the ground-glass. Here, however, it must be pointed out that if the whole camera is pointed upwards we shall get a distorted view. The top of the church is further from the lens than the lower portion, and therefore will appear smaller in proportion, with the result that upright walls will slant towards one another on the ground-glass just in the same way as the sides of the road do, but the latter appears in correct perspective and the former will look absurd. This is corrected by always keeping the back of the camera level and vertical, and if this is done, perpendicular lines in the subject will be vertical in the image, however much the lens is tilted upwards.

In using the rising—or cross—front, we use the margins of the light-circle made by the lens, and as this portion of the image is usually not so well defined as the centre, it may be necessary to "stop down" the lens, that is, to reduce its aperture, in order to get sharp detail.

When using the swing-back vertical when the lens is pointed upwards, it will be noted that the part of the ground-glass where the image of the top of the building falls is farther from the lens than the part where the lower portion of the building is projected. Now, to get the maximum sharpness in the image, the ground-glass should be closer to the lens for a distant object than for a near one. So when the swing-back

is employed for getting proper uprights in a photograph, we are reversing the normal order of things as regards focussing.

Fig. 2.

and the image will therefore be a good deal "out of focus" in some parts. For that reason, again, it is necessary to stop down considerably to correct the want of sharpness. Usually the amount of stopping down required is less in the use of the rising front than in employing the swing-back. That is to say, the latter requires a much smaller aperture (which means longer exposure) than the former, so that the rising front is preferably used where the lens will produce a sufficiently good marginal image. Very often it happens that either of these movements alone will still not include as much of the upper part of the subject as is desired, and in such cases the only

thing is to slide the lens up as far as it will go and then point the camera upwards till the required view is obtained, when the ground-glass is brought to a vertical position again by means of the swing-back. This combined movement calls for a very small aperture in the lens, and care should be taken that the bellows do not cut off part of the image. They are usually provided with rings to hook on to the camera-front to prevent sagging in this way.

To get the maximum sharpness after adjusting the camera as described, an easy way is to mark on a strip of gummed paper on the baseboard when the lens is focussed on the most distant part of the subject, then mark again when the nearest part is sharp. Then rack back two-thirds of the space between these two marks, and use the smallest aperture of the lens.

The best kind of level to employ in getting the swing-back

Fig. 3.

Fig. 4.

perpendicular is one with a cross level let into one end of it A, or a small level may be fixed to one side of a piece of wood very accurately cut to a right-angle B (Fig. 3). This level is placed just against one side of the camera, as in Fig. 3, and the centre leg of the tripod moved to get the bubble central. The leg is moved in the direction the bubble is required to go. Then the level is placed against the ground-glass (Fig. 4), and the back swung till the bubble is again central.

D. CHARLES.

(To be continued.)

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

- A Talk About Lighting (Jan. 3).
- The Camera and the Lens (Jan. 10).
- Managing the Sitter (Jan. 17).
- Backgrounds (Jan. 24).
- Studio Exposures (Jan. 31).
- Artificial Lighting (Feb. 7).
- Printing Processes for Portraiture (Feb. 14).
- Studio Accessories and Furniture (Feb. 21).
- The Surroundings of the Studio (Feb. 28).
- Studio Heating and Ventilation (March 7).
- The Postcard Studio (March 14).
- The Printing-Room (March 21).

- About the Reception Room (March 28).
- Home Portraiture (April 4).
- Portable Studios (April 11).
- Copying (April 18).
- Handling the Studio Camera (April 25).
- More About Lenses (May 2).
- Enlargements (May 9).
- Advertising the Studio (May 16).
- Mounts and Mounting (May 23).
- Business Methods (May 30).
- Photographing Children (June 6).
- Portraits of Elderly People (June 13).

SOMETHING ABOUT LENSES.

The lens is the most important item in a photographer's outfit; it is also the one about which he knows the least, and he often pays dearly for his ignorance. There are so many varieties of lenses—or perhaps I might more correctly say lens names—that a mere list of them would go far to fill the space allotted to this article, so that I will not attempt to enumerate them all, but to deal with the characteristics and capabilities of those which are most likely to be met with by the photographer in the ordinary way of business.

Portrait lenses will naturally be of the greatest interest to the majority of my readers, and I may point out that at the present day there are many which may be included in this class, although they are not listed under the special name, for there is nothing distinctive about a portrait lens, except the feature of a comparatively large aperture, which allows of short exposures being made indoors. I am inclined, therefore, to class as portrait lenses all which have a maximum aperture of not less than *f*/6. The old type of portrait lens, often called the Petzval, after its original designer, is

of little use for anything but studio work, as when used out of doors with a moderately small aperture it was prone to give a pronounced central flare spot which was fatal to good work. Still, the smaller sizes up to 8 or 9 inches focal length are sometimes used successfully upon reflex cameras when very short exposures are required, the full aperture of $f/3$ or $f/4$ being then employed. They may also be used for copying photographs or other subjects where absolute rectilinearity of the lines is not essential. This type has a deeply curved field and considerable astigmatism at the edges of the field; therefore it should not be pushed to the limit of its capacity; a good specimen will, however, cover a field the diagonal of which is about two-thirds the focal length of the lens to be used. For example, a ten and a-half or eleven-inch lens will do very well at a fairly large aperture for a cabinet picture, assuming this when trimmed to measure $5\frac{3}{4} \times 3\frac{3}{4}$ inches. For very short studios, therefore, it is better to employ an anastigmat which will cover a much larger field without stopping down. Curvature of field is not such a serious objection in portraiture as in other classes of work, as the subject is not all upon one plane, and the curvature allows of the face, hands, and knees being sharply rendered with a larger aperture than can be used in a flat field lens, although the latter would give better general definition with a standing figure. Although I referred to the matter last week, it is worth repeating that the front combination of a portrait lens used alone gives a good image with slightly softened definition, and has a focal length of about one and a-half times that of the complete lens. It is useful to remember this when it is desired to make a rather larger head than usual when only a short-focus lens is available. The exposure required will be about double that of the complete lens, and, if perfectly sharp definition be required, a slight reduction of the aperture will be necessary. The quickest portrait lenses have an aperture of nearly $f/2$ and the slowest $f/6$, the latter being also adapted for groups, and under favourable conditions to outdoor work. Several makers have issued portrait lenses which are adjustable to give a soft image if wished.

All the more rapid forms of anastigmat answer excellently for studio portraiture, but care should be taken not to select one of too short focal length. Good perspective or "drawing" is only to be obtained by the use of a fairly long focus lens, and the mere fact that the plate is perfectly covered is of little moment compared with this. Unfortunately, extra rapid anastigmats are very costly in the larger sizes. Referring to the pre-war list of one maker, I find a 16-inch $f/4$ portrait lens quoted at £26, while a 15-inch $f/4.5$ anastigmat costs £30, the next size larger, an 18-inch, being still more expensive—namely, £40. The covering power of the latter is, however, much greater, and they are free from flare; hence they will also serve for outdoor work on large plates.

Besides portrait lenses, properly so called, there is a class known by various trade names, such as Euryscope, Universal Symmetrical, Portrait Aplanat, etc. These are of the rapid rectilinear construction, but have apertures of $f/5.6$ or $f/6$. They answer well for portraiture, but their field of sharp definition at full aperture is limited. If one having a focal length nearly twice the longest side of the trimmed print is selected, it should be found satisfactory. These lenses are free from flare, and when stopped down will do all the work of a rapid rectilinear. It is worth noting that the appellation "Aplanat" only means that the lens is free from central spherical aberration; it does not denote any anastigmatic or "flat field" properties. I mention this because in some quarters there is an impression, often fostered by dealers, that an aplanat is a variety of anastigmat. A generation ago Grubb applied the term to single lenses and rectilinears.

Rapid rectilinears having apertures not smaller than $f/8$ are frequently used for large sizes in portraiture, and with

the fast plates now available are quite rapid enough in action. Even when more rapid lenses are used, it is generally found necessary to reduce the aperture when taking large heads, in order to obtain depth. At one time it was averred that rectilinears gave an image which lacked plasticity and had a "cut out" appearance; but this opinion does not seem to be held nowadays.

Single lenses are sometimes employed in artistic portraiture, and if used at a sufficiently large aperture give a pleasingly soft definition between the sharpness of the ordinary lens and the pronounced fuzziness of the anachromats. Old landscape lenses of large diameter can often be very cheaply purchased, and after removing the fixed diaphragm, which is usually about $f/16$, are ready for use. As I propose to deal with soft-focus portraiture as a separate subject, I shall not deal with lenses specially constructed for this work in the present article.

For groups many types of lenses are pressed into service, the portrait lens being the least suitable, as its curved field renders a special arrangement of the sitters necessary, while the small aperture which has to be used to get even passable definition to the edges of the plate make it very slow in action for studio exposures. Rectilinears do better at the same relative aperture, but it is here that the anastigmat is seen at its best. With a good lens and a judicious use of the swing back it is possible to secure uniform sharpness throughout with a comparatively large aperture; but one precaution is necessary—that is, to use as long a focus as the studio will allow, otherwise the figures in the front row will appear noticeably larger than those in the back; and this is generally objectionable, even to the untrained eye of the client. The photographer should never accept the optician's classification of lenses as regards the sizes covered, as the excellent quality of most of the newer lenses justifies the makers in listing a nine-inch lens for whole plates or a 13-inch for 12×10 ; but if such lenses were used for close-up groups on the size of plate indicated, the perspective would be bad, although the definition might be perfect. I cannot too often repeat that the quality of a lens has nothing to do with the rendering of perspective, this being solely a matter of focal length in relation to the size of plate used. The cheapest single lens and the most perfect anastigmat, if of equal focal length, will give the same perspective at the same distance from the group upon the same size of plate. It is purely a matter of angles, as an experiment with a pinhole will prove. If we arrange a group of articles—sacks, boxes, or whatnot—and take photographs with a nine-inch lens and with a pinhole placed at nine inches plus the addition to the back conjugate necessary for the nearness of the object, we shall obtain exactly the same drawing. The moral is to use for all work as great a focal length as conditions will allow.

There is a host of other models which have their various uses in outdoor and interior work, copying, etc., but which are of little value for portraiture. Rapid rectilinears I have already mentioned, but they may be used for nearly all photography where the greatest rapidity is not essential. Architecture copying, catalogue work, and landscape are all within their scope, and if of good quality they will be found little inferior to anastigmats. Wide-angle rectilinears and portable symmetricals are designed for work in confined positions, as buildings in narrow streets, interiors, and for copying. They usually have an initial intensity of $f/16$ only, and this is to my mind a serious drawback, as it is often difficult to focus a dimly lighted interior with so small an aperture; therefore, I advise that when expense is not a primary consideration, small anastigmats with apertures of $f/7.7$ or larger should be used. It is easy to focus with these at full aperture, and to stop down to obtain the neces-

sary depth of field; another advantage is that the lens is available for rapid work on a smaller plate; thus in my own practice I use a 5½-inch anastigmat as a quarter-plate hand camera lens, and also as a wide-angle lens on a whole plate, while an 8-inch serves in the same way for half-plate and twelve by ten.

An old type of lens not now made, but frequently to be met with, is the triplet, or triple achromatic. It is a splendid copying lens, good for architecture, landscape and groups; in fact, it will do all that a rapid rectilinear will do, and at equal apertures I even fancy the general definition it gives to be superior. Its great fault is slowness, the full aperture being usually $f/12$. This, however, is not a great objection for the larger sizes of plate, as considerable stopping down is usually necessary to secure depth.

Single or landscape lenses deserve more consideration than they usually receive from professional photographers.

They have two faults—slowness, the full aperture being usually $f/15$ or $f/16$, and a tendency to curve straight lines near the margins of the picture. In the best makes the latter defect is not present to any harmful extent if the focal length chosen is at least as much as that of a rectilinear lens made for the size of plate to be used. The great advantage of the single lens is the crispness and brilliancy of the image which is obtained in outdoor work, especially open landscape. If we take a first-rate modern lens and an old wide-angle landscape lens and give both identical exposures upon a well-lighted open subject, the latter will win every time on points for the quality of negative. Still, we cannot carry round a bagful of lenses, and so the single combination one is often left at home; but one often feels that, after all, it would be wise to bring it along when on view work pure and simple.

PRACTICUS.

COLOUR VALUES IN MONOCHROME, AND A NEW VIEWING FILTER TO ASSIST IN OBTAINING THEM.

[The following paper, read by Mr. F. F. Renwick before the Royal Photographic Society, deals with a problem which is always present in the translation of colours into monochrome. The author's exposition of recent research will help to make clear the complex nature of the problem and the orthochromatic worker will welcome the promise of more definitive methods which is contained in the latter portion of the paper.—EDS. "B.J."]

(Continued from page 336.)

This was done by first plotting Abney's scale numbers against the wave-lengths corresponding thereto to obtain the calibration curve (Fig. 3) of his instrument. Now the length of normal spectrum included between the jaws of the slit is, at any point, proportional to the tangent to the above calibration curve at that

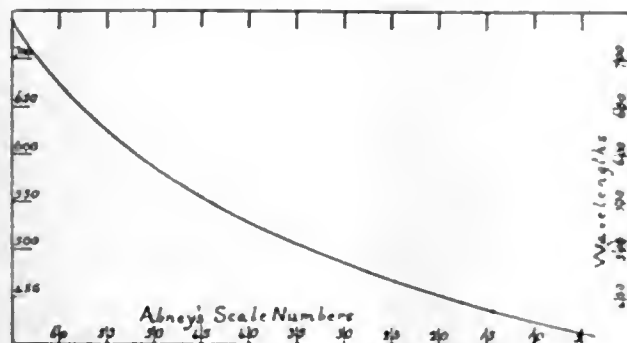

Fig. 3.

point and, for such narrow bands of the spectrum, the required corrected luminosity value at any point may safely be taken as being inversely proportional to the wave-length interval included by the slit.

The ratio of the tangent to this curve (Fig. 3) at any point to the tangent at $\lambda 585$ (Abney's scale number 50, which he took as his standard of luminosity = 100) is therefore the number by which Abney's observed luminosity value must be multiplied to arrive at the corrected luminosity for that point; this corrected value will correspond to equal small sections of a normal spectrum and leave unaltered the value of his standard. These ratios are most conveniently expressed as logarithms, which have only to be added to the logarithms of Abney's observed luminosities to yield the logarithms of the corrected luminosity values.

Thirteen such tangent ratios were found for points five scale numbers apart along the calibration curve, and their logarithms plotted against the corresponding Abney scale numbers; a smooth curve was then drawn through the points. From this curve (Fig. 4) the logarithm of the correction factor can be read off for any point of the spectrum.

In the table are given:—

- Col. 1.—Abney's scale numbers.
- Col. 2.—Corresponding wave-lengths.
- Col. 3.—The luminosity values given by Abney in Table IV., col. 4, of his book, page 94.

Fig. 4.

- Col. 4.—Logarithms of the values in col. 3.
 - Col. 5.—The correction factor, corresponding to the region of the spectrum, which has to be added to the value given in col. 4.
 - Col. 6.—The sums of the values in cols. 4 and 5.
- It will be observed that the effect of these operations is slightly to shift the apparent position of maximum luminosity, found by Abney at $\lambda 585 \mu\mu$, towards the blue, to $\lambda 572 \mu\mu$. To bring back all these corrected luminosities to a maximum of 100 it is, of course, necessary

Notes. — Figures in brackets refer to Abney's Table 38, p. 239, col. 3. The figure in the third decimal place in the correction factors is only approximate.

in this case to deduct .021 from all the logarithms in col. 6, thus giving col. 7 in the table. In col. 8 the anti-logarithms of the figures in col. 7 are given, these being the percentage luminosities of the different regions of a normal spectrum (arc light) expressed in terms of the corrected maximum at $\lambda 572 \mu\mu = 100$.

These numbers, if plotted against their corresponding wave-lengths, show the curve of distribution of luminosity of the normal spectrum of the light from the positive crater of the electric arc which Abney used. Similar tables and curves may easily be derived from several other series of Abney's experimental data by means of the correction factors given in col. 5 of the above table, and I have worked out several in this way.

It will be observed that the position of maximum luminosity lies almost exactly at the middle of the visible normal spectrum ($\frac{\lambda 390 + \lambda 760}{2} = \lambda 575$) and especially that this continues to be true

even with a spectrum so enfeebled that most of the red end has become invisible (Abney's Table VI., p. 98). We shall see, too, that the distribution of luminosities on either side of the maximum is nearly symmetrical in both cases.

It would be very interesting to know the curve of luminosities for a number of sources of "white" light after the eye is fully adapted to each, for it is well known that the eye readily accepts as white any of a wide range of lights, differing considerably in colour from one another, in the absence of a standard of comparison.

Instead of plotting relative luminosity values against corresponding wave-lengths, it is more useful to us to plot their logarithms, because the curve so obtained corresponds to eye estimates of relative brightness, just as photographic densities (logs opacity) are better than opacities for studying and appreciating the gradation of negatives and prints; moreover, the changes at the feebly luminous deep red and blue ends of the spectrum are more clearly displayed by this method. Fig. 5 shows the two curves of corrected luminosity logarithms corresponding to the data given in Abney's Table IV., col. 4, p. 94, and Table VI., p. 98 (for a feeble spectrum), after modification in the manner already explained. The full figures for the former curve are given in col. 7 of my table above. For these sets of observations the eye was dark adapted.

Several interesting conclusions may be drawn from these curves, for they represent also the relative values of the densities which should be produced by the spectrum of the light of the open arc on a panchromatic colour-sensitive plate which has been corrected by means of a filter perfectly adapted to it. In other words, given any panchromatic plate, what we have to do is to make a filter for it which will so modify the light of the open arc positive pole that the above curve represents the distribution of densities obtained in a spectrogram made on the plate by that light. Further, in the case of a plate possessing even sensitiveness throughout such a spectrum, the inverse of this curve gives the absorption coefficients (D in the equation $I = I_0 \times 10^{-D}$) of the required filter for every wave-length merely by re-numbering the ordinates downwards, beginning with zero at the central maximum, as I have done at the right-hand side of Fig. 5.

Fig. 5.

Clearly for a uniformly sensitive panchromatic plate a strong green filter is the only one which could lay any claim to be a perfect correcting filter for all colours, and inasmuch as recent advances in the production of panchromatic plates have resulted in the realisation of equal sensitiveness in the red and blue of the spectrum of arc light, with the green not far behind, it is evident that for the best work in monochrome a green filter is now absolutely essential.

Another very interesting application to be derived from such curves is as follows:—In those cases where use of the full correction filter is impossible or thought to be undesirable, it would often be useful to have filters for observation purposes which would so modify the relative luminosities of the scene or object to be photographed that the latter appeared in the same sequence of brightness to the eye as the plate, or plate and screen, about to be used will portray them. With approximately monochromatic

filters (i.e., appreciably narrower in their region of transmission than the tricolour filters used in three-colour work), inspection of the scene through the filter to be used will usually be sufficient to give the desired information if the plate shows no insensitive gaps or other marked irregularities of sensitiveness to the spectrum; but where these exist or with any plate when a comparatively pale filter embracing a wide region of the spectrum is to be used, such a procedure is most misleading, and the frequently offered advice to use them in this way cannot be too strongly condemned.

II, however, we construct a filter having absorption coefficients

Fig. 6.

corresponding to the inverse of, i.e., complementary to, the perfect correction filter, for any given panchromatic plate, it will reduce the apparent luminosities of every part of the visible spectrum of white light to correspond to the sensitiveness of the plate to the same light. Hence such a filter will so alter the appearance of any coloured scene or object that its apparent tone values will now agree with those which the panchromatic plate would register.

For an evenly sensitive panchromatic plate this will mean a filter having absorption coefficients corresponding with the curve of Fig. 5, or Abney's luminosity curve expressed logarithmically. Obviously, such a filter would have a violet colour complementary to that of the perfect green correcting filter already described. Fig. 6 shows diagrammatically for an imaginary plate the relations which exist between V, the curve of visibility of the spectrum, P the curve of sensitiveness of an imaginary colour-sensitive plate, P-V the absorption curve of the perfect correction filter for monochrome rendering, and V-P that of the viewing filter under discussion, for such a plate as P within the wave-lengths limits considered, viz., 400-700 $\mu\mu$. If such viewing filters were made to correct all colour values fully up to the limits of the visible spectrum they would be too dark for convenient use; further, since action on a photographic plate occurs beyond the visible spectrum in the violet, even this degree of correction would not be sufficient. In practice, however, I find it to be possible for the best modern panchromatic plates to construct filters transmitting sufficient light for convenient observation, and yet capable of serving as valuable aids in judging the order of luminosities which the plates will record. Owing to the slightly inferior green sensitiveness of even the best commercial panchromatic plates, the absorption curve of the observation filter required for them should pass rather less green light than Fig. 5 indicates. The presence of ultra-violet sensitiveness and the absence of sensitiveness in the deep red beyond about λ 720 are best allowed for by passing more blue light as compensation for the former and cutting out the deep red completely on account of the latter fact, so that the required filter will have a fairly deep blue violet or blue hue.

With a properly balanced filter of this kind we can see beforehand what kind of record our unscreened plate would give us, and by adding any desired yellow, orange, or other filter to it can study the effect of such filter on the rendering of the tone values of the scene by the plate. In this way we are enabled with greater certainty to select the filter required to produce any desired tone relationships. I have prepared such filters as are here described both for full correction and for observation purposes, and have pleasure in showing them to-night, but the main object of this communication will have been fulfilled if it serves to direct attention to certain interesting aspects of the problem of rendering colour in monochrome which do not appear to have received much attention hitherto.

F. F. RENWICK.

EXAMINATION QUESTIONS IN PHOTOGRAPHY.

[The following are the questions set at the examination held by the City and Guilds of London Institute, in the Ordinary Grade of Photography, Section B—via. Photo-Mechanical Processes. We have appended answers of a kind which students of this degree of knowledge might reasonably be expected to give. The questions (and answers) in pure photography were given in our issue of June 13.—EDS. "B.J."]

SECTION B. PHOTO-MECHANICAL PROCESSES.

GRADE I.

1. You are given the opportunity of selecting and testing before purchase lenses intended for (a) making of half-tone negatives, (b) making line negatives. Explain exactly what properties you would specify, and how you would proceed to demonstrate whether or not the instruments fulfilled the requirements laid down. (50.)

The same lens is generally used for half-tone and line negative-making. If the lens is to be used entirely for line work there is not so much necessity for it to work at large apertures as is required for half-tone work.

Process lenses must be specially corrected as they are nearly always used for moderate reductions, same size, or enlargements. The wet plate process being used very extensively for line and screen negative, and this method requiring an excess of blue and ultra-violet rays to secure quick exposures, the glass employed in the construction of these lenses must be transparent to this portion

of the spectrum of white light. The focus of the lens should be somewhat long, otherwise the oblique rays towards the edge of the plate may interfere with the correct dot formation. The process lens should give critical definition at full aperture over the size plate it is stated to cover, and be free from spherical aberration, shown by the detail at the edge of the negative being in focus as well as that in the centre; also from distortion, shown by straight lines on the edge of the field being reproduced straight. It should be free from the oblique aberration of coma and radial astigmatism which is shown by the marginal portion of the field being correctly and sharply defined; also free from chromatic aberration, the coloured images of white light being sharp and in focus at the same time. To examine the lens for these defects a test object should be made of a number of squares ruled on white paper, and this test object be focused up to various sizes and the image inspected to see if any changes take place in the image when the stop is reduced, that the definition is equally good all over the plate, and that all straight lines are reproduced as straight. A few wet plate negatives should be taken to ascer-

tain that the reproduction is as sharp as that shown on the ground glass.

2. Why is it necessary, in the first instance, to make an ordinary photograph from an object in relief when it is desired to illustrate that object by means of the ruled screen half-tone processes? Your answer must be in detail and not merely generalities. (5.)

The half-tone process reproduces as a very flattened scale of gradation. An object in relief presenting an extended and steep scale of gradation, it is necessary first to obtain an ordinary photograph of a relief object in a somewhat flattened scale to enable the correct dot formation to be secured in the screen negative.

3. Name some of the substances which have been proposed for use and have actually been used in the making of filters for correcting the undue blue sensitiveness of the ordinary dry-plate of commerce. (15.)

The following dyes or chemicals can be used: picric acid, bichromate of potash, Auramine, Naphthol Yellow, Tartrazine, Flavacine T., and Yellow filter A.

4. What is the object of the preliminary graining of the zinc plate prior to coating it with bichromated colloid for zinc line printing? (15.)

To give a porous surface to the zinc which will hold grease or water, and also to enable the sensitive solution to be flowed evenly over the plate and give a grip to it when dry.

5. Given two nap leather rollers as they come from the makers, state how you would prepare them as "starting" and "finishing" rollers, respectively, for line relief etching. (30.)

One method of preparing a new nap roller is as follows:—First indicate on the handle the direction of the nap and thus make sure that the roller is always scraped with the nap. Roll into the skin Russian tallow and allow to remain until absorbed. When absorbed, roll up with equal parts of tallow and mid-litho varnish, gradually increasing the varnish until all varnish is used. Scrape well, and then apply equal parts of varnish and ink, increasing the quantity of ink until all ink is used. Give a good scraping, and the roller is ready for use. At first it is as well to only use it on coarse work.

A finishing roller is generally an old litho roller with the nap worn off. Before being used it is rubbed down smooth with sandpaper and finally polished with the hand.

6. What is meant by "direct" photo-lithography as against "transfer" photo-lithography. Describe in detail one method in each process. (50.)

Direct photo-lithography is the process in which they greasy ink image is obtained by printing on a bichromated albumen film held on a special zinc or aluminium plate, through a reversed line or half-tone negative. In the transfer process the greasy image is secured by printing through a direct negative on to a bichromated gelatine film supported on paper. The ink image is then transferred either to stone or metal. The advantage of the latter process is that the actual greasy image comes in contact with the litho stone or plate; whereas in the former method of working the image has a thin film of albumen between it and the metal.

The following is the method of working the two processes. Zinc plates for the direct process are supplied especially grained, and before coating are placed for a few minutes in a cleansing bath of water, 20 ozs.; nitric acid, 1 oz.; and alum, 2 ozs.; after which they are removed and placed under water and swabbed over with a tuft of cotton-wool. A plate is then ready to receive the bichromated albumen which is made up of the white of one egg, or 75 grains of dried albumen; water, 20 ozs.; fish glue (Le Page's), 11 minims; bichromate of ammonia, 130 grs. This solution is well beaten up and the froth allowed to settle, and then carefully filtered. The metal plate is fixed on a special whirler and the sensitive solution poured on and quickly whirled, and then dried by gentle heat. It is then exposed under the negative in a pneumatic frame to a strong actinic light. After exposure it is rolled up with a special photo-litho ink and the plate placed under water, and then carefully rubbed over with a tuft of cotton-wool. The portion where the light has struck the ink will be retained; on the other portion it will wash away, leaving a greasy image of the original on the plate. The plate is then gummed up, dried, and is then ready for the prover.

In the transfer process some special photo-litho paper is required, which is sensitised in a 2½ per cent. solution of bichromate of potash, made light yellow by the addition of ammonia. The paper is left in this sensitizing bath for three minutes, it is then withdrawn and squeezed on to glass or a ferrotype plate to give a glazed surface. The exposure, rolling up, and developing, is the same as for the direct method. After development the transfer is dried, and is then ready for the transferer.

7. Name the substances which can be used for producing an image on zinc suitable for line relief etching. Which process is considered to be the best, disregarding the elements of time and cost? (30.)

The substances used for producing an image on zinc for the line relief process are—sensitive bitumen, bichromated fish-glue and bichromated albumen. The bichromated albumen is the best and quickest for the general run of work.

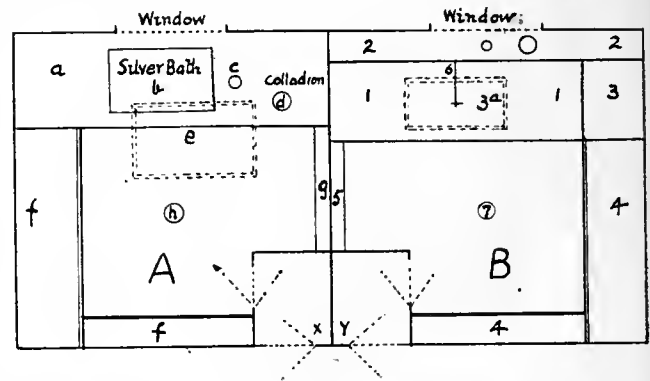

8. State the differences between the kinds of dry plates which can be used for making negatives of line drawings. What essentials must a plate fulfil to be suitable for the work? (30.)

The difference between the dry plates used for process is, that the ordinary process plate is chiefly sensitive to the ultra-violet and blue rays of white light, and the panchromatic process plate to all colours of white light. A process plate must be capable of giving great density coupled with fine grain and thin film. In those known as "half-tone" plates the thin film is very necessary.

9. Give a simple sketch of the arrangement and specify the equipment for (a) a sensitising room, (b) a developing room for wet-plate work. (60.)

A.—Plan and Equipment of Wet Plate Sensitising Room.

(x) Entrance lobby, with two swing doors opening both ways to enable the operator to enter room without admitting light.

(a) Table for silver bath and collodion bottle and filter.

(b) Silver bath.

(c) Small hole through table to support glass funnel when filtering bath, the bottle in which bath is being filtered is under table.

(d) Collodion bottle and draining bottle.

(e) A large yellow safe-light is hung from ceiling of room, 7 to 8 feet from floor.

(f) Tables to hold dark slides, having shallow ledge to prevent dark slides slipping down. Two or three drawers should be fitted to these tables in which can be placed blotting paper, bath hooks, etc.

(g) Ledge or shelf.

(h) Electric lamp suspended from ceiling.

B.—Plan and Equipment of Wet Plate Developing Room.

(y) Entrance lobby as for A.

1. Large sink made of teak wood or porcelain.

2. Ledge or shelf over sink to hold developer bottles and pouring cup.

3. Shelf over sink to hold fixing bath, or bottle containing fixing bath.

3a. Safe-light suspended over sink at such an angle to enable operator to follow flow of developer.

4. Tables for dark slides with projecting edge.

5. Shelf for bottles, etc.

6. Tap which projects well over middle of sink to enable negatives to be handled without knocking back of sink.

7. Electric lamp suspended from ceiling.

General remarks. The dark rooms should be painted black or terra cotta colour, and be well ventilated with light trap ventilators, both top and bottom of room. The windows are glazed with a special orange glass or fitted with a frame on which is stretched orange fabric.

All tables should be well varnished with a chemical-resisting varnish.

10. What is the object of supplying a substratum to glass for wet collodion negative making. What materials are used for the purpose. (15.)

The object of applying a substratum to the glass used for the wet collodion process is to hold the collodion film on the glass and prevent it stripping off when placed in the silver-bath; also, when the glass has been cleaned, and then substratumed, it can be stored and is always ready for immediate use. Albumen, gelatine, and, sometimes, a thin solution of India rubber dissolved in benzole are used.

11. What are the principal conditions governing the sensitiveness of the coating prepared by means of a bichromated fish-glue mixture. (50.)

The conditions governing the sensitiveness of the bichromated fish-glue film are: that the bichromate of ammonia used in the glue should not exceed 6 per cent.; that the glue be free from acidity and impurities; and that the film is dry and not coated too thickly.

12. Describe the means which are available for producing a facsimile of the effect of a line drawing by the line relief process when the original shows varying depths of tone in the lines constituting the drawing. (30.)

The following is a method of obtaining a reproduction of a line original showing varying depths of tone in the lines. A negative is made through a fine screen or Metzograph screen, aiming to eliminate the dot effect in the black lines, and retaining a small hard dot in the grey lines, and a strong join in the high-lights. The negative is printed by the enamel process on zinc and burnt in, full exposure being given. The print on metal, if correctly exposed, should show the strong lines as a solid, the grey lines with a dot or grain effect, and the white minna a dot or only a very fine one. This print on metal is etched so as to obtain depth and correct tone in the grey lines, after which it is treated as a line etching, any dots showing in the white being etched away. After mounting, the metal plate is carefully routed to eliminate any portion of the plate representing the white card or paper of the drawing, otherwise these parts are liable to print up in the resulting proof.

Photo-Mechanical Notes.

Photo-Engraved Advertising Novelties.

Do engravers get their proper share of the business in manufacturing the advertising novelties that are so constantly in demand? Photo-engraving is especially suitable for making the placards shown on shop counters, on the walls, and in the windows, but most of this work is pure lithography and does not have the faithfulness that photo-engraving would have. Package goods, bottles, and small objects carefully reproduced and printed in colour, two, three or four colour, look extremely attractive and the colours used often need only be flat tints. Such jobs as these, however, should be undertaken by the engraver in conjunction with a good printer, and the job quoted for as a whole, to include the delivery of the finished work.

Etching of designs in the same way as name plates can provide a great variety of novelties such as rulers, penknife handles, backs of blotters, ash trays and so on, and brass or nickel-silver is just as easy for the engraver to etch as his familiar zinc or copper, so that the only thing he has to learn is to fill in the design properly.

There is also a field for enamels, the metal being etched from a design and the powder enamels being filled in the etched hollows and fused in the furnace, though, perhaps, this is rather a long way away from the ordinary routine of the engraver. However, the making of prints on metal and their nice mounting is nearer home, and some excellent advertisements have been made in this way. For example, a neat line drawing with a black sky and black street

has been made of a place of business. This is photographed and an ordinary line print made on aluminium, dusted with bitumen, heated until glossy, varnished with transparent varnish, and mounted on a piece of bevelled mahogany and provided with a support. The finished article is a charming novelty at very little expense. Or if you desire to show tone, any photograph can be used, a half-tone positive made, and this etched so that you have an intaglio print. The hollows are now filled in with japan or other suitable black, and you have a permanent and attractive advertisement. This field should be decidedly worth cultivating.

Reproduction of "Matt-Surface" Originals.

EVERY half-tone engraver—or, indeed, anyone making copies—knows the difficulty of reproducing satisfactorily matt-surface copies, a difficulty which is increased when the colour of such originals happens to be sepia or brown, as it so often is. The result is usually of a peculiarly disagreeable "graininess," to which the customer very much objects. This is caused by the scattering of the light due to the matt surface. It cannot be minimised very much by the use of elongated stops, as roughness in the picture itself apart from the surface may be; and the only thing to remedy it is to treat the surface so as to do away with the light-scatter.

The writer has found a very satisfactory way to varnish the print with a waterproof varnish (called in the U.S.A., "Kodaklak"), applied to the print just as collodion would be flowed over. A thin celluloid varnish would no doubt do as well, though probably not for prints made on matt collodion paper. The drawback to this method is that the print is permanently "de-matted," so to speak, and if the customer objects to this, some other means must be found. The most satisfactory is the use of glycerine, which can afterwards be removed with a little water—when the print will dry up as it was before treatment. The best way of using this method is to flow the print and then squeegee the print into contact with a piece of plate glass, being careful to squeeze out all air bells. Encaustic paste may also be used, but this has the disadvantage of the varnish in being difficult to remove, and also is somewhat difficult to apply evenly and free from streakiness and lint.—A. J. N.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications June 2 to 7:—

CINEMATOGRAPHY.—No. 14,161. Cinematograph apparatus. T. M. Down

PHOTOGRAPHIC APPARATUS.—No. 14,431. Photographic apparatus. B. T. Lang.

COLOR CINEMATOGRAPHY. N. 14,132. Preparation of cinematograph films and projection of motion pictures in colours therefrom. L. O'Malley.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

FOLDING CAMERAS.—No. 125,818 (June 13, 1918). The door or closure piece through which the lens projects when in its extended position is divided into two hinged mounted parts opening away from one another, the amount of opening movement of each part being limited. There is a stop piece upon each door and one or more spring clips adapted (when one end of a plate-like part supporting the lens and the front end of the camera bellows is brought against one of the stop pieces) to yield and allow the other end to be brought against its stop piece, when it rises to engage the rear side of the plate and hold it in position against the stop.

In the drawings the door or closure piece for the aperture in

the camera body through which the lens and bellows project when the latter are extended is made in two parts *a*, *b* hingedly mounted so as to open away from one another, curved arms *c* limiting the opening movement of the doors. Each door carries one or more stop pieces *d*, *d'* at its outer end and one or more plate springs *e*, *e'* project adjacent to said stops.

The lens *f* and front end of the bellows *h* are carried in a member *g* acting as a slide (for adjustment purposes) within a front plate *i*, which is brought into its correct position for use by placing one end between, for example, the stop *d* and plate spring *e* on the door *b* and then using that end as a fulcrum whilst the other end is turned to a corresponding position, the spring *e'* at the free end being displaced until the plate abuts against the stop *d'*,

when it rises at the rear and bevelled edge of the plate and prevents its withdrawal, unless the spring is displaced by hand when it is desired to return the bellows to their folded condition. The plate *i* may be adjusted from side to side of the camera by sliding it between the springs *e*, *e'*, and stops *d*, *d'* and the lens be adjusted by moving the plate *g* in the plate *i*. The latter may carry the finder *j* or this may be attached to the lens.

If desired, the one door may have a groove only therein which serves as a stop and holder for the one end of the plate *i*, whilst the other door has the spring *e* and stop *d* as herein described. Suitable spring catches hold the doors in their closed positions.—Samuel Poole Twemlow, Springfield, Sandbach, in the County of Chester, engineer.

ELECTRIC RETOUCHING PENCILS.—No. 125,832 (J. 28, 1918). A lead pencil or other suitable pencil is loosely mounted and carried in a tubular holder at the top of which there is a box or casing containing an electro magnet with an oscillating armature which is electrically oscillated by the electro magnet. The top end of the pencil is so situated relatively to the free end of the armature as to be struck thereby, but in order that the blows from the armature on to the pencil may be muffled an indiarubber cushion is introduced and fixed on to the top of the pencil or on to the end of the armature, and in addition to this the lower end of the pencil which projects through the tubular holder is supported by a spring which permits of the necessary slight and rapid longitudinal oscillations of the pencil in the holder.

In carrying the invention into practice an ordinary lead pencil 1 of the refillable type is employed, and is mounted loosely in the tube 2, forming a tubular holder, the upper end of which tube fits in the tubular clip 3, which is fixed to the bottom of the case 4, containing the electro magnet 5, which is arranged with its axis parallel with the axis of the pencil. This electro magnet is suitably connected to a battery, and is combined with an ordinary make and break device in the case 4 and the oscillating armature 6, arranged at the top of the electro magnet, one end 7 of the armature being fixed to the bracket 8 of a back plate 9, on which the electro magnet is fixed. The free end 10 of the armature is situated over the upper end of the pencil 1, which

latter is fitted with an indiarubber cushion block 12, adapted to be struck by the armature so that the vibrations of the latter will be muffled and transmitted to the pencil 1, but in a smaller degree. The lower end 13 of the pencil projects through the bottom of the tubular holder 3, and is there secured for rapid longitudinal vibrations by means of a spring, which is preferably formed of a strip of thin indiarubber 14, which at 15 is bound on to the projecting lower end of the pencil, and also at 16 is bound on to the end of the tubular holder 2, so that this indiarubber spring supports the pencil in the holder, with the indiarubber

block on the upper end of the pencil at the proper distance from the free end 10 of the oscillating armature 6.

When using the electric pencil above described it is preferred for the case 4 to be suspended, as at 18, from some overhead point by a cord 17, combined with a short length of indiarubber acting as a spring suspension piece adapted to relieve the weight of the box and its contents on the user's hand. The best results on the negative can be obtained by using a moderately hard lead 19 in the pencil, and with a fine point on which the muffled vibrations are so small as to be almost invisible to the naked eye.

The intensity of the vibrations on the pencil caused by the armature can readily be adjusted by sliding the tubular holder 2 in the clip 3, so as to cause the indiarubber block 12 on the top of the pencil to be slightly nearer to or farther from the armature 6, this clip 3 being furnished with a set screw 20, passing through the two ears 21 of the clip, by which the latter can be tightened or slackened on the tubular holder 2.

It is found that the arrangement above described acts well in practice, but if desired in addition to or instead of the indiarubber block 12 being fixed on the top of the pencil 1, there may be an indiarubber block fixed on the outer end 10 of the armature 6 to strike the pencil and form the muffled vibrations.—William Henry Franklin, 5, Castle Street, Dudley, Worcestershire.

PHOTOGRAPHERS SCARCE.—At an inquest at Lambeth on Saturday last, on the body of an unknown man found in the Thames, the coroner asked whether the police had had the man photographed, and was told that it would take 24 hours to get a photographer. The coroner said that a photographer ought always to be available, adding that photographs were not taken as scientifically as they might be.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JUNE 21.

Chelsea Photographic Society. Affiliation outing in Croydon district.
Liverpool Amateur Photographic Association. Outing to Pool Hall, near Hooton.
Manchester Amateur Photographic Society. Outing to Poondawick.

MONDAY, JUNE 23.

South London Photographic Society. "Working up the Negative and Print"
E. W. Taylor.

TUESDAY, JUNE 24.

Hackney Photographic Society. "Hints in Composition." H. Lamplough, sen.
Manchester Amateur Photographic Society. "Woodland Photography." J. D. Berwick.

THURSDAY, JUNE 26.

Hampshire House Photographic Society. "Garden Portraiture." S. Taylor.

CROYDON CAMERA CLUB.

THE informal session began last week, Mr. E. Cahen giving a lecture on "Cordite," in the production of which he was actively engaged during the war. Many things contributed to the suppression of the Hun, but even the most earnest advocates of home-grown potatoes as a means towards victory would admit that cordite occupied a useful niche of its own.

Briefly, the manufacture of cordite can be divided into three main parts: The making of the gun-cotton; the making of the nitro-glycerine; and the combination of the two. As is well known, the first is made by treating cotton with mixed nitric and sulphuric acids. The product is boiled and washed many times to remove last traces of acid, otherwise it might explode before utilisation in the required direction, which would be disappointing. It is then pulped and dried. The second element is made by nitrating glycerine with great care in cold, well-stirred solution with the same acids, and is then washed with water and dilute soda, and stored in lead tanks.

Weighed amounts of nitro-glycerine and gun-cotton are first mixed by hand and then transferred to incorporating machines, where acetone and a little mineral jelly (vaseline) are added. The resulting paste is pressed through dies of suitable sizes, and the finished cordite is cut into lengths to suit the guns for which it is required, and finally dried.

In a cordite factory, he said, the words "sulphuric acid" and "nitro-glycerine" are seldom heard, being respectively referred to as "oleum" (owing to its oily look) and as "the oil." Recovery of the acetone and acids is a strong feature, as upon this depends the commercial success of the factory. The latter in general appearance looks like a waste of sandhills dotted with separated small houses, and lined with miles of steam piping. Two areas are divided by danger-gates, and striking matches, etc., in the danger area is not appreciated.

In the discussion it was cheering to note that no topic of whatever nature comes amiss to the members. Mr. Purkis, apparently approaching the subject for the first time, and, therefore, not being bound by conventional ideas, suggested several important improvements in procedure. Cordite, being essentially an element whose virtue is dependent upon the liberation of gas at the psychological moment, naturally attracted Mr. Harpur, who waxed eloquent on "teasing the cotton." Why cotton should be teased he failed to explain, but this led Mr. Ackroyd to ask whether an early drop in price of sewing cotton might be expected, but the lecturer knew not. Those who are more or less compelled to sew buttons on their own unmentionables can only live in hope that the perilous economy of material obligatory in these days may be relieved in the immediate future. A most hearty vote of thanks was accorded Mr. Cahen, proposed by the president, who paid a tribute to the excellence of the photographs taken by the lecturer, many under extremely difficult conditions.

TYNESIDE PHOTOGRAPHIC SOCIETY.—Under this title a photographic society at Newcastle has been formed, open to both sexes. The subscription fee is 10s. 6d. for seniors and 5s. for members under 21 years of age. A progressive programme has been outlined for the summer and winter sessions. The hon. secretary is Mr. J. Nichol, Dial House, Newcastle-on-Tyne.

Commercial & Legal Intelligence.

NEW COMPANIES.

P. F. PERRY AND Co., LTD.—This private company was registered on June 6 with a capital of £4,000 in £1 shares. Objects: To enter into an agreement with P. F. Perry, and to carry on the business as manufacturers of and dealers in photographic and scientific apparatus. The subscribers (each with one share) are:—P. F. Perry, 11, Church Street, West Hartlepool; R. W. Hudson, 15 South Road, West Hartlepool, company adjuster. Directors: P. F. Perry and R. W. Hudson. Registered office: 11, Church Street, West Hartlepool.

NAVANA, LTD.—This private company was registered on June 5 with a capital of £10,000 in 9,500 10 per cent preference shares of £1 each and 10,000 ordinary shares of 1s. each. Objects: To carry on portrait and general photographic studios. The subscribers (each with one preference share) are:—A. Bennett, 67, Wokingham Road, Reading, photographer; T. B. Kitson, 72, Albion Street, Leeds, solicitor; A. E. Walsbam, 60, Doughty Street, W.C., photographer. Directors: A. Bennett, T. B. Kitson and A. E. Walsbam. Registered office: 60, Doughty Street, W.C.1.

News and Notes.

PHOTOGRAPHING THE AIR.—Photographs showing air in motion across the wings of an aeroplane, taken with a moving picture camera equipped with a recently invented device, were put in the hands of Mr. Crowell, Assistant Secretary of War, just before he sailed from New York for Europe. The photographs were made in a series of experiments with army aeroplanes, and are expected by officers to prove of value in designing and operating aircraft.

"PUNCH" has discovered the following in the "Transactions" of a photographic society:—

"Mr. — stated that as Architectural Photography covered a large and varied field he purposed to confine his remarks to the line of work most familiar to him, namely, The Interior of some of the great English Ministers."

This leads "Punch" to comment:—

"Now at last we shall know if the Government's heart is in the right place."

THE OPTICAL BRANCH of the Ministry of Munitions has been transferred to the Board of Trade, and the latter will deal with questions of assistance to, and organisation of the optical scientific instrument, glass, and potash industries, including administration of the Glass Control (Consolidated), Clinical Thermometer, and Potassium Compound Orders. All communications relating to such questions in future, therefore, should be addressed to the Assistant Secretary, Board of Trade, Industries and Manufactures Department, Scientific Instruments, Glassware, and Potash Production Branch, 117, Piccadilly, London, W.1.

PHOTOGRAPHY AND THE RETAIL BUSINESS LICENSING ORDER.—In reply to an enquiry addressed to the Controller of Retail Business Licence Order we have received the following information which, we trust, will be useful to many of our readers.

"I am directed to inform you that no licence is required for the four branches of photography mentioned. If it is desired, however, to sell frames or photographic accessories a licence will become necessary. The above ruling applies uniformly throughout the country (Ireland, which does not come under the Order, excepted)."

The four branches referred to are:—1. Photographic portrait studio. 2. Photography away from the studio, of various subjects such as landscapes, machinery, etc. 3. Portraiture at sitters' homes or in public places, for example, on Hampstead Heath and other pleasure resorts. 4. Retouching of negatives.

CONTINUED RATIONING OF COAL, GAS, AND ELECTRICITY.—The Controller of Coal Mines announces that it is found necessary to continue the rationing of coal, gas, and electricity for household fuel and lighting for a further period. It is, however, proposed to modify the present order to the extent that consumers of less than 5 tons of coal in the year, 12,500 cubic feet of gas in any quarter,

400 B.T.U.'s of electricity in any quarter, will not be subject to assessment. They must, however, be registered with their coal merchants for the supply of coal.

A revised Order, which will take effect from July 1st next, will be issued during the present month. In the meantime the following memorandum is issued for the information of the public.

1. Anthracite, coke and patent fuel will be exempted from the Order for the time being.

2. All consumers of coal must register with coal merchants for their supplies. Present registrations will be valid unless notice to the contrary is given by either consumer or merchant.

3. The present assessments are current for a year from various dates commencing with October 1st, 1918. In the case of consumers over the quantities named above, the assessments will be renewed for the same annual quantity for 12 months from July 1st, 1919, and the balance of the old assessments cancelled.

4. New certificates will be issued to all present holders of certificates for the 12 months' supply, and it will not be necessary to make application for the certificates, except in the case of new consumers or of those who, owing to a change in the basis upon which the original assessment was made, desire a modified assessment.

5. The new assessments and certificates will date from 1st July in order to enable private consumers, so far as coal may be available, to stock on account of the coming year's allowances. Immediately on the issue of the new order, arrangements will be made to enable this to be done during the months of July, August, and September.

6. The supply of fuel already made under any existing certificates in respect of the period subsequent to June 30th will be treated as a supply on account of the new year's allowances.

7. The conversion equivalents of gas and electricity in terms of coal will be fixed at:—18,750 cubic feet of gas to the ton of coal; 1,000 B.T.U.'s of electricity to the ton of coal.

8. The control of maximum prices for the sale of coal will be rigidly enforced.

9. In order to simplify some of the machinery and provisions of the present Order, the special Local Fuel and Lighting Committees will be discontinued, and, in the ordinary course, the control of the Local Fuel Overseer will, subject to the directions of the Controller, be left to the local authority—except in the Metropolitan Division, which will continue under the immediate supervision of the Household Fuel and Lighting Branch of the Coal Mines Department.

Economy in the consumption of coal still remains vital to the national interests. If the output of coal in the near future will allow a relaxation of those restrictions, the Local Fuel Overseer will be authorised, from time to time, to receive applications for such increased allowances as any increase in the supplies of coal may justify.

Correspondence.

PHOTOGRAPHERS' ANNUAL HOLIDAYS.

To the Editors.

Gentlemen,—I am pleased to inform you, that the Londonderry professionals have agreed without exception to close down their studios for August Bank Holiday week. This is the second year of the innovation, and the eagerness shown by each and all fellow professionals for continuation of the scheme well repaid the little trouble spent in going round.

Surely most small provincial towns could do the same if one man would make a round of his fellow professionals and induce them to start a similar scheme. My advice is try it, we are not such a bad lot when we meet.—Yours faithfully,
E. G. HARRIES.

THE LONDON SALON OF PHOTOGRAPHY.

To the Editors.

Gentlemen,—In view of the forthcoming Salon of Photography may I draw attention to a small detail in the hands of the Selection Committee which in my opinion calls for alteration? As all exhibitors know, their accepted and rejected prints in passing before the Committee are scored on the back with the welcome A and less welcome B and C, together with figures concerning the cataloguing of the same. Of recent years since framing has been abolished the black chalk with which this is done occurs on the back of the prints or mounts themselves. When these are placed on the top of each other in the processes of rejection, storing or re-packing, the chalk may, and all too frequently does, transfer itself to the surface of the print to which it lies in contact. When this is a delicate bromide print the effect is often to do serious damage, since the chalk is extremely difficult to remove, even with rubbing under water, and even when this remedy is successful, as far as the chalk is concerned, it has the disadvantage of removing any hand work upon the print, even if it does not remove the emulsion!

I am sure this point has only to be realised to be easily corrected either by marking with a different material or by placing thin paper between the prints.—Yours faithfully,

AN EXHIBITOR.

STEREOSCOPIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—The concluding paragraph of the article on "Stereoscopic Photography" in the June 6 issue of the "B.J." tends to convey a wrong impression, to which C.E.B. will, no doubt, be glad to have his attention drawn.

The idea in your contributor's mind is to make large size negatives and then reduce them to obtain improved apparent definition at the normal interocular separation. He suggests that these large pictures should be taken at "a view-point separation of 4 ins. to 6 ins."; the assumption being that the subsequent reduction would cause the consequent relief to be correct. This assumption, however, is wrong; no matter what the size of the picture may be, providing the relief required is normal, the separation should not exceed that needed for the ordinary stereogram.

Perhaps C.E.B. will give his opinion on this matter for the benefit of readers who, like myself, have read his most instructive article with the greatest interest.—Yours faithfully,

H. J. MOBBS.

41, Ravenscourt Gardens, W.6.

[Mr. Mobbs is perfectly right, and I am obliged to him for calling attention to the point. The view-point separation should be the same for two half plates as for the direct stereogram if the normal separation is to appear in the reduction. It is, of course, recognised that for special subjects involving distant objects it is often permissible and advantageous to increase the view-point separation beyond the normal, but this applies as much to direct stereograms as to large photographs that have to be reduced.—C.E.B.]

ASSISTANTS' WAGES.

To the Editors.

Gentlemen,—The letters of "Assistant" and "An Employer," which have appeared in the correspondence columns of the Journal of May 30 and June 13 respectively, are, to say the least, interesting.

I will go a little higher than "Assistant" and say that £3 per week for capable and competent workers, which has been offered in recent issues of the "B.J.P.," is an inadequate wage. This is less than 30s. according to pre-war value. How can employers expect capable and competent workers to take a real interest in their work for a wage which barely assures them an existence?

Assistants—like employers—are only human, and is it natural to expect assistants to put any heart in their work from which they derive no pleasure?

We read in our daily papers of street sweepers and lamplighters getting 64s. and 74s. per week (good luck to them). Probably we shall be told this includes war bonus. But isn't the assistant worth a war bonus, seeing the cost of living is still on a war-basis?

Many of us have done our bit overseas, and instead of finding conditions better when we come back we find them comparatively

worse. If this is the result of the war it is time we had another war—at home.

We also know that the "war product" is a "wash-out." Employers will also find this out during the next few months. Probably some have already found it out.

In the last report of the P.P.A. Council meeting Mr. Read is reported to have remarked that it should be made known to parents of the bright prospects and good appointments to be had in the profession. This was said 20 years ago. But how often are parents told that many of these "good appointments" include Sunday work? And at the present rate of wages one sees offered there doesn't seem to be very much "good" about them.

With regard to "An Employer," it is rather refreshing to find one who is willing to give a useful hint or two, and I hope "Assistant" will accept the offer and benefit thereby. And if "An Employer" cares to extend his offer, you are quite at liberty, gentlemen, to forward the address of yours faithfully,

ANOTHER ASSISTANT.

To the Editors.

Gentlemen,—In contradiction to "An Employer," whose letter appears in June 13 issue on the above subject, let me say that I do not "doubt," but that I have ample proof of a number of firms trying to get competent and capable men for quite as little as the £2 a week quoted by "An Assistant" in his letter of May 30, "B.J." p. 303. The trouble is that these employers do not want "war products," but efficient men at war product prices. I certainly consider the glut of incapable assistants responsible to a great extent for this order of things, since men who are out to learn something at an employer's expense are ready and willing to offer their inferior services for what sounds a small salary, and this debars the man who sets a proper value on his professional knowledge from getting a berth until he is so hard up that he is forced to accept a smaller wage than he ought to receive, with the result that some lucky employer gets the benefit of his brains, and should this assistant die or leave, the employer wonders how it is he gets such a lot of "duds" before he picks up another like him at the price.

Now for the particular sentence which causes me to write this letter. "An Employer" says, "... I doubt if actual promises were made by any employers to keep places open for patriotic assistants, unless in a few rare and exceptional cases." Whatever has prompted any sane man to pen such a statement? Does he read the advertisement columns of his "B.J." at all? If so, I presume all the firms who tell us they can get on with business as usual now their old staffs are "demobbed" and back at work again are all liars! At any rate it seems clear that "An Employer" is not one of the few rare and exceptional cases himself.

Before he makes any more of these weak remarks let "An Employer" ponder over the following:—"Another Employer" at the outbreak of war enlisted in the ranks with his men, and fought and bled with them; and since demobilisation, six weeks ago, has hastened to re-instate those who have not made the great sacrifice, and he does not consider himself either a rare or exceptional case, although he admits he made no actual promises to his men, for fear an iron ration from Fritz would prevent him from fulfilling them.

I won't question how many operator-retouchers at £5 a week "An Employer" has on his staff, but perhaps he will inform us how many printers and assistants he employs, and what he pays them? If any operator-retouchers who have been unable to find £5 a week berths have not spent all their War Gratuity in stamps looking for a job, perhaps some of them may care to consult "An Employer," because I am sure he must be in a better position to advise them than the unfortunate two pounds a week people he offers to give hints to.

Let "An Employer" think again, and perhaps he may realise that operator-retouchers are not general assistants who must be able to do anything (including operating and retouching), and that it is these men upon whom so many businesses depend, and who are generally paid so much beneath their actual worth; and if he has any hints to offer concerning them, let him publish them through the same splendid medium he has made such rash statements in, and thus earn the gratitude of assistants who ask a fair wage, and employers who are in the profession for more than mere money.

Yours faithfully,

ANOTHER EMPLOYER.

June 16, 1919.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

R. W. D.—No effect is produced upon the cards by using rubber gloves. We know of no better way of protecting the hands.

J. M.—Cards such as you require are made in various processes and in large quantities by Messrs. Hood and Co., Sanbride Works, Middlesbrough.

E. H. N.—The vignette you have in your mind is evidently the "Bram" made by Messrs. Wahltuch Smith and Co., Ltd., 30, Chapel Street, Salford, Manchester.

J. H.—1 It is not necessary for the backing to be dry, but it is advisable to put a piece of brown paper between the plates to prevent the spring on the partition from scratching off the coating.
2 Brush out with a dry shaving brush and then wipe over with a slightly damp cloth.

E. T. C.—There is no book on tank development. Broadly, the method is to dilute the developing solution, as used for dish development, with water so that development takes from 15 to 20 minutes. It may be necessary, with many formulae, to make up the stock solutions with an extra proportion of sulphite in order to avoid stain in the tank developed negatives.

E. B.—Blisters such as appear on your films are often caused by a change in temperature and also density of liquid. If a plate or film is transferred from a warm, rather strong, hypo bath to cold water the blisters are likely to occur; in the weather we have been having solutions become warm. The fogging may also be due to a high temperature in the dark room. We have seen several cases of this lately.

H. B.—We do not recommend putting the half-watt lamps into the circular reflector as they will be then in too much of a bunch. We think that five 1,000 c.p. lamps will be quite sufficient, and you might fix three of these along the beam and two on a cross bar the same height running across the studio so that one is nearly opposite to the centre of the background. This bar should be about 7 ft. from the background.

N. W. T.—We are afraid there is no method of focussing with a full aperture. These lenses are not very highly corrected, and you cannot depend on getting critical definition by focussing at full aperture and exposing with a small stop. The best thing you can do is to use a good magnifying eye-piece for focussing—for example, a Ramsden eye-piece as sold by Messrs. James A. Sinclair, Ltd., 54, Haymarket, London, S.W.

R. W. D.—Unless the business is carried on in the names of yourself and your partner you require to register it. In this case you should apply to the Registrar of Business Names, 39, Great Russell Street, London, W.C.1. The cost of registration is 5s., and you will have to put the names of yourself and your partner on your business stationery, but you need not put them on mounts or post cards nor display it on the front of the premises.

Vox.—The retouching medium can be removed by rubbing with pure turpentine and a clean rag. It is necessary to do this thoroughly, and a second application is advisable; the negative may then be reduced or intensified as usual. The pencils used for working on

enlargements are the ordinary chalk or carbon pencils, or Conte crayon will do if the pencils cannot be obtained. The spots on the gaslight prints are probably due to minute air bubbles. Swab the print over with a pad of cotton-wool the instant it goes into the developer.

E. L. J.—Provided the photographs were taken to the sitter's order, and the usual rates of payment made, then the copyright belongs to the sitter, who can do what he likes with the photographs without any acknowledgment to the photographer. On the other hand, if the sitter was invited by the photographer to have a free sitting and afterwards purchased copies, the copyright in that case belongs to the photographer. For full information on the copyright question we would advise you to obtain the manual, "Photographic Copyright," issued by our publishers, price 1s. 2d. post free.

M. N. J.—Mercury vapour is a very bad light for projection, since the light is very greatly diffused instead of being at a single point as it is in the ideal illuminant for projection. Evidently, what you want is an ordinary high-power right-angle projection arc such as you can get from Mr. R. R. Beard, 10, Trafalgar Road, Old Kent Road, London, S.E., an experienced lanternist as well as a thoroughly reliable maker. In writing to him you want to find out from your local electrical people what amperage you can carry on the main at your disposal. Knowing that, you can select the arc accordingly.

B. W.—If the blind is in such a bad condition as to give the leakage represented by the negative—and that seems to be the only likely cause—we think that no dressing will put it in proper condition—at any rate, permanently. The usual dressing in such cases is a little rubber solution mixed with the finest lampblack. But we should think it is a case for a new blind, such as a firm like Messrs. H. T. Ball and Co., 52, Berwick Street, Oxford Street, W. 1, could fit. The Planar is rather a back number in lenses owing to its great liability to flare; the value of an 8-in. at the present time is probably not more than four or five pounds. We do not think there will be any advantage in dead-blackening the sheaths, the spots not having the appearance of being caused by them in any way.

INCANDESCENT GAS, ETC.—Would you kindly advise me how to light studio by incandescent gas, number of burners required and arrangement of same, also if a lens $f/5.65$ is suitable for the studio 12 feet in length?

You will need 12 or 15 burners to get reasonably short exposures. Suitable lamps for your purpose are the "Powerful" of Messrs. Kodak, Ltd., Kingsway, W.C.2, the "Howellite" of Messrs. Griffin, Ltd., Kemble Street, Kingsway, W.C.2, or that of Messrs. Tress and Co., Ltd., 4, Rathbone Place, Oxford Street, W.1. If you write to any of these firms they will send sketches. If you will state size of plate to be used and focal length of lens we can answer your second question. Twelve feet is very short for a studio if you want to make full-lengths.

C. E. W.—We should certainly recommend you to get a half-plate camera with as long an extension as possible, say 20 inches. With this you would require a good rapid rectilinear lens of about 8½-in. focal length and a 4¾ or 5-in. wide angle rectilinear. The R.R. will answer for the majority of subjects, and the front or back lens may be used alone for the bottles, jars, etc., for which you need a long-focus lens. The wide-angle is for interiors and outside views in confined situations. Have nothing to do with supplementary lenses for serious work. Enlargers just now are costly, but an adjustable daylight enlarger might be picked up cheaply, or you might enlarge by using your camera against a blocked-up window if you have a suitable room. You could of course take quarter-plates with the half-plate camera, and enlarge these in a small enlarging lantern with 5½-in. condenser, which would cost you about £7 or £8. But enlargements from small negatives are apt to look rather coarse for catalogue work, most of which is done direct.

FRILLING.—Would you be so good as to let me know what you would consider the best remedy for the softening and consequent frilling of films during hot weather? Would it be harmful to films (or gaslight prints) to put alum in the acid fixing bath—as the

films are often very soft before they even get to the washing stage? I use hypo. and metabisulphite for the fixing and metol-hydroquinone for developing—using the fixing bath for films after it has done service for print-fixing. Alum in the fixing bath would be the solution if it did not harm the film.

In hot weather most people use a fixing-hardening bath, formula for which is as follows:—20 ozs. saturated solution of alum, 4 to 7 ozs. saturated solution of sodium sulphite, and from 20 to 28 ozs. of hypo solution containing 1 part hypo dissolved in 5 parts of water. A bath of this kind should be sufficient to prevent softening of the films so long as they are handled as little as possible with warm fingers. Messrs. Johnson and Sons, 23, Cross Street, Finsbury, E.C., have just brought out a "tropical hardener" which is diluted to make a bath in which plates or films are soaked for three minutes before developing. A bath of this kind might perhaps suit you better for use when the temperature requires it, whilst leaving your customary arrangements (developer and fixing bath) undisturbed.

G. G.—With regard to the length of exposure, this is partly accounted for by the distance the lamps are from the sitter, and still more by the fact that you have opal diffusers, which stop nearly all the actinic quality of the light. The remedy will be to remove your lamps to the positions marked by the stars on your diagram, and to replace the opal by *thin* white calico. 3,000 c.p. does not allow much light to waste. If you are trying to work by reflected light only you will have to get the sitter about three feet from the wall. Your statements about distances for various sizes are unintelligible to us. What is the equivalent focal length of the lens, and what is the maximum aperture? The fog you complain of may be due to many causes besides faulty plates. Try developing an unexposed plate in absolute darkness for five minutes with a normal developer, and see if it fixes out clear. Also test your dark-room light; not a quarter of the red lights in use are safe for really rapid plates. Get a dozen fresh Imperial special rapid plates, and if you get foggy negatives with them you will know that the plates are not to blame. As regards the slowness of development, this seems to indicate that the solution is too weak, either from use or age. Make up fresh solution, and do not dilute so much if it still works slowly. Twenty minutes should be enough for tank development. Strengthen the solution so as to give full density in this time.

SUMMARY.

Some points to be observed in the selection of wide-angle lenses, particularly with respect to the actual angle included, are noted in a paragraph on page 361.

The first portion of a practical article on the compounding of photographic solutions, dealing with weights, measures, percentages and other points will be found on page 365.

A very simple system of silvering mirrors which does not call for extreme purity of materials, and which is claimed to be very reliable in hot climates, is detailed on page 370.

The hand-camera is not so generally utilised by professionals as it might be. In his article this week "Practicus" gives hints on the capabilities of various types and their applicability to otherwise difficult subjects. (P. 368.)

The case for the employment of dry-plates in process work as being expeditious and economical is very clearly demonstrated in a paper on page 370.

Photographs on wood blocks are often required for catalogue work, and those who undertake them will find details of a simple process on page 372.

The final section of the article on camera movements deals mainly with the use of the swing back as an aid to focussing with large apertures. (P. 364.)

An application of an old photographic trick which may be turned to account by commercial photographers is described on page 362.

A paragraph dealing with the desirability of standardising the etching time for half-tone blocks so as to secure uniform tone and depth appears in "Photo-Mechanical Notes" on page 370.

A description of an easily-made focussing screen for fine detail such as is necessary in photo-micrography is given in a contributed article on page 363.

At the last meeting of the Professional Photographers' Association several points of interest were discussed, the question of specimens and an assistants' union being the principal ones. (P. 372.)

The new sizes of plates and a plea for the Petzval portrait lens are subjects of letters by our correspondents. (P. 375.)

Lens matters, studio lighting, and the clearing bath for platinum prints are dealt with among other subjects in "Answers to Correspondents." (P. 376.)

The specification of a patent flash-lamp of the type in which a match is used for igniting the powder is given with illustrations on page 371.

EX CATHEDRA.

Wide-Angle Lenses.

There still appears to be a good deal of ignorance upon the subject of wide angle lenses, many photographers being at a loss when it comes to choosing a lens or lenses for exceptional subjects. Roughly speaking, a wide-angle lens is one which covers a plate the measurement of the longest side of which is greater than the focal length of the lens to be used. Thus a six-inch lens may be considered as embracing a wide angle upon a half-plate, this being 55°, allowing $\frac{1}{2}$ in. rebate. Usually, however, much wider angles are embraced; many rapid anastigmats give an angle of 80°, while some of the types of wide-angle symmetrical will give 100°. Beyond this we have only the Hypergon, which gave about 130°, but was never much used, as the resulting perspective was grossly exaggerated. When the extreme angle of a lens is given in a catalogue it should be ascertained whether this is calculated for the base of the plate or the diagonal, as otherwise a lens embracing a less angle than is necessary may be selected. For example, if we wish to use a whole plate we may have to choose between two lenses of equal focal length, one being stated to have an angle of 90° while the other claims for 78° only. Yet if both be used upon a rectangular plate, exactly the same amount of view is included, the former angle being only obtainable in a circular picture, which is seldom required. We have sometimes found it useful to use a plate a size larger than the lens is supposed to cover and to cut from the circular image so much as can be utilised. Thus, with a four-inch rapid rectilinear a panoramic view 8 x 3 ins. can be obtained upon a whole plate, and by blocking out the sky so as to cover the dark corners a greater width could be used.

Side Lines.

We fear that in the past photographers have allowed many opportunities of adding to their business to pass by without knowing it. Particularly is this the case with regard to photo-mechanical work, such as half-tone blocks and printing and collotype. In many cases they have made negatives to order for a comparatively small amount; from these, orders amounting to perhaps hundreds of pounds have been executed, often by people who are merely agents, who make a handsome profit by handing them over to firms actually producing them. In pre-war days quite a large business was done in this way with German collotype printers, a large proportion of the view postcard and catalogue business being handled in this way. As soon as the commercial world settles down to serious work there is bound to be a large demand for illustrations by manufacturers and others, and we hope that our readers who have a connection with such people will endeavour to keep the whole

business in their own hands instead of merely assisting at the start. They will need to see that they do that, for many printing firms will send operators to make negatives of, or at, a factory, when the local photographer, if sufficiently awake, might have secured the entire job. We do not believe that many photographers have troubled to acquaint themselves as to the various ways in which photo-mechanical prints can be made, much less to provide themselves with full sets of specimens in different styles. Almost any kind of print can be imitated in collotype, from a glazed P.O.P. to a platinotype, and for less costly work fine half-tone work comes in a good second. There are several English firms who will undertake this work for photographers, who then have only to secure the order and pocket their profit, which may be anything from 10 to 20 per cent. This may seem small compared with portrait profits, but it must be remembered that such orders are usually for large amounts, and that even at the smaller figure there is £20 to the good on a £200 order. A branch in which many will feel more at home is in handling large orders for bromide prints. The wholesale firms who use machinery for producing these can quote prices which will leave a substantial profit, and the work can be relied upon for uniformity.

* * *

Panchromatics and Speed.

There seems upon the part of many professional photographers a decided reluctance to the use of panchromatic plates. Perhaps one reason for this is the idea that the exposures are unduly long for portrait work. This is really not the case, and if in exceptional circumstances the exposure would be unduly long, with a K2 filter—which is perhaps the most generally useful—the screen may be omitted altogether and a result produced that will be far in advance of the ordinary non-ortho plate. In fact, a panchromatic plate, if used without a screen, is equal to one of the special rapid variety, and will produce a result equal to the orthochromatic plate with a four or five times screen. In practical work this is a great advantage when only partial colour correction is required and the speed of the plate has not to be sacrificed. Panchromatic plates should always be used, either with or without a screen, when working out of doors late in the day, when the light is inclined to be yellow or red, and will show a marked increase in sensitiveness over the non-ortho grades. In this respect the panchromatic plate should prove of service to press operators.

* * *

Duplex Exposures.

The old method of trick photography by means of which the same person may be shown in two or more positions upon the same plate is well known to most photographers, but a recent inquiry as to the best way of setting about it suggested an application which in some circumstances would be of practical value and not a mere curiosity. For the benefit of those who may not understand to what we refer, we may explain that it is quite easy to make photographs in which a man may be playing a game of chess with himself, or a lady standing and singing while she also appears to be seated at a piano, playing the accompaniment. This is done by the simple expedient of providing the lens with a very deep box hood with two flap shutters overlapping very slightly in the centre. One of these is closed and the sitter taken in the first position; it is then closed while the sitter moves into the second position, when the other shutter is opened and the exposure made. The two halves of the picture then appear so perfectly vignetted into each other that no junction is visible. The application suggested is that this trick may be employed when it is

desired to take two views of any object without a line of demarcation appearing between them. For example, the front and back of a vase or statue or two views of a piece of machinery may thus be taken, or a figure photographed in front and behind for a fashion plate. A little practice may be necessary to get the exact amount of overlap, as if this be too great there will be a rather lighter band down the centre and if too little a dark line, but this can easily be adjusted. The necessary fitting can be made of cardboard and must be well blackened inside.

BUYING SECONDHAND APPARATUS.

THE business in the purchase and sale of secondhand apparatus has probably never been upon so large a scale within the memory of photographers as it has been of late and is likely to be for some time to come until the normal output of manufacturers is restored. Hence a few notes on the purchase of apparatus may not be out of place. A prospective buyer has two courses open to him in supplying his wants. According to the first, he may watch the advertisements of goods which are offered, or himself insert an advertisement of what he requires, or, according to the second, may state his requirements to the dealers in second-hand requisites. There is something to be said for both methods. In dealing with strangers it should be an invariable rule not to send money, but to insist that the transaction should pass through the deposit system of the paper in which the advertisement appears. Certainly something may be gathered from the style of an advertiser's letter-heading or writing, but it does not need much knowledge of human nature to know that a favourable impression in either of these respects may be created by a rogue. There is, moreover, the trouble of getting goods on approval and of coming to an agreement with the advertiser as to the payment of carriage in the event of their not being purchased. On the other hand, the price asked by a private advertiser is very often less than that required by a dealer, and the would-be seller, if he can find a reliable purchaser, would rather dispose of his goods in this way than to a dealer, on account of the better price which he gets. There is nothing contradictory in these two statements since a dealer's price when purchasing is usually one which provides a very ample margin against the contingency of the money represented by the goods lying idle for a long period until a re-sale is effected.

The advantages that the dealer offers are many. Having a large stock, he can nearly always supply a camera or lens of almost any required pattern from stock. In most cases a guarantee is given that it is in good condition in the case of a large dealer. The apparatus may be had on approval and tested to the user's complete satisfaction without the fear that might reasonably be entertained about an unknown stranger that sharp practice or reluctance to release any deposit may cause a lot of trouble before the affair is finally settled.

Before taking the various classes of apparatus in detail a word may be said about the price. At the present time, owing to the almost total absence of new goods from the market, second-hand apparatus is fetching a high price. In some cases recently cameras and lenses have been fetching more on the second-hand market than they did a few years ago when brand new. We think many photographers lose sight of a very important point when buying apparatus, and that is how the particular goods appear in the light of an investment; how they will re-sell in the event of their owner having no further use for them. In this the old axiom is true: that the best is always the cheapest. At the present time old or out-of-date apparatus may be bought for a pound or two. What will be

its value a year or two hence!—possibly only a few shillings. Then those whose habit it is to compare prices will often find that one particular pattern of camera and lens, or lens alone, for that matter, may be quoted at a certain price. Another of the identical type may be quoted by the same or another firm for perhaps twenty-five per cent. less. It must not be inferred that the one is a bargain and the other excessively dear, because the reverse may actually be the true order of things. In fact, the price asked by a reliable firm may be taken as a criterion of the quality of the goods. If two models are priced as described above by competing firms it may be assumed that there is something about the one instrument that makes it worth more than the other. The camera or lens may be of more modern pattern; or, if this is not stated, it is almost certain to be in the better condition. We have seen apparatus on the market that, knowing the trouble that will arise from its use or the cost of its repair, even assuming that such is possible, we should consider dear at any price, and in this way the reputation of an established dealer becomes of real value to the prospective purchaser.

Coming now to the defects to be looked for in apparatus of various descriptions, field or studio cameras require to be examined for warped, split, or scratched woodwork, worn, bent, or loose-fitting struts. The bellows should be carefully looked at; what is described as leather may actually be imitation leather or cloth. The camera should be racked out to its fullest extent in a dark room and an electric bulb placed inside it in order to test the light-proofness of the bellows. The latter, if old or worn, will be found to be loose and to sag, and are then certain to give a good deal of trouble in the way of cut-off. Rigidity of the back and of the front of the camera when erected are specially important points, and the intending purchaser

will hardly neglect to examine the focussing mechanism for smoothness of movement. A camera which has had a good deal of wear, or has been roughly used, will allow of the focussing heads being turned through an appreciable angle without any corresponding movement of the front or back, as the case may be. This "backlash" makes accurate focussing by no means a matter of certainty. In the case of folding focal-plane cameras a feature of prime importance is rigidity of the strut system by which the front is held extended. If this is defective a satisfactory repair may cost quite as much as will discount any benefit from the purchase. In testing the shutter of such cameras the intending purchaser should not omit to try it at the lowest speed. A shutter which may work satisfactorily at the maximum spring tension may prove erratic at the lower speed as a result of weakening of the springs. Here again it requires to be borne in mind that the repair of a focal-plane shutter is usually somewhat expensive.

In case of book-form slides attention should be given to detect warping. In one case we knew a double mahogany book-form slide had warped to such an extent that it could not be inserted in its grooves in the back of the camera. The slide should be held quite close and firmly by its catches, preventing the admission of light. Any shrinkage of the woodwork will cause the springs or catches to hold loosely. If the two halves of the slide may be moved with the catches in position shrinkage of the wood has taken place, and it should be regarded with suspicion. The draw-out shutters should work smoothly in the grooves. In the case of metal slides the draw-out shutters should be examined with a view to detect dents or abrasions, which, owing to the very slight clearance may scrape the surface of the plate when being drawn out. Vulcanite draw-out shutters should be examined for pinholes, which have been known to appear after a course of ill-usage.

A FOCUSsing SCREEN FOR PHOTO-MICROGRAPHY

THE ordinary fine ground-glass screen, when used for daylight landscape and portrait photography, is satisfactory enough, but the photo-micrographer needs to get an exceedingly sharp image, far surpassing in that respect what is necessary for the photographer. The method of first arranging the subject on ground glass and substituting a piece of polished plate glass, on which to obtain, by means of a properly focussed magnifying glass, a critically sharp aerial image, though perfectly satisfactory, is a somewhat troublesome method. Another well-known method is to cement with Canada balsam a small microscopic cover glass on the ground surface, in any position that suits the fancy or requirements of the photo-micrographer. This method is also fairly satisfactory. But the following method of preparing a focussing screen has in my hands produced a screen combining the advantages of both the above. Moreover, should an accident happen to the screen, or the plain surface become scratched from the continued use of the focussing glass, a new screen can be made very quickly. The process is a slight modification of the method which I gave in a photographic annual of 1892. I there wrote:—"Expose a dry plate of the required size to gaslight for a second or two, then develop until a slight grey deposit is obtained, wash and fix; wash, and when dry the surface will be found admirable for a screen." The modification consists in retaining certain portions of the film to fix out clear. I prepare the mask by pasting on a clean, say, half-plate glass a central opaque disc of paper of 2-inch diameter, and concentric with this a ¼-inch ring of similar opaque paper of maximum

diameter, 2½ ins. When dry, this is placed in a printing frame, like a negative, and the half-plate lowered, film downwards, on to the papered side. Exposure is made, and the plate developed until there is a well-marked deposit, and this is easily gauged owing to the clear ring and disc. When fixed, washed, and dried, the screen is complete, and is a joy to use. The Rev. F. C. Lambert considers it necessary to polish the film by means of an iodine and iodide of potassium solution. This, I think, is a mistake, as the grain of the plate

is rendered coarser by the conversion into iodide. Moreover, Mr. Lambert scratches away the film to obtain clear glass. This is a troublesome business, and also wrong theoretically, as it changes the plane of the image, though in practice this is negligible. The figure will no doubt render the matter quite clear. The diagram shows the clean glass, with central disc and ring of opaque paper, and the resulting screen will, of course, be the positive of this negative.

With this arrangement a sufficient amount of the object can

be seen in the annular space to get a rough focus, and the portion selected for photography can be arranged to fall within the outer ring, with the certainty of being within the compass of a 3-inch lantern slide mask. Of course, the final critical sharpness is obtained with the focussing glass. It is also a

convenience to make a dot or small cross with ink on the film side in the centre of the clear disc. This not only indicates the centre of the photograph, but is a test for the proper adjustment of the focussing glass.

G. ARDASEER.

CAMERA MOVEMENTS.

III.

In Section II. the swing-back was shown in use for a specific purpose in which it unavoidably upset the performance of the lens, and thereby called for much stopping-down, and consequently increased exposures. In this section it will be shown how in subjects where vertical lines do not exist the swing-back can be employed to help the lens, and allow it to be used at a large aperture with short exposures as a result.

In portraits it is usual to have the lens above the centre of the subject, and pointing slightly downwards. It is only when using a reflex, for instance, or a snapshot camera, that it would be held level with the waist for a full-length figure. For portraits the camera is generally somewhere about the same height as one's own face is. This is not intended to teach the art of portraiture, which is a separate subject altogether, but it will be seen that it is necessary to point the camera downwards, because otherwise too much space would be included above the head, and the falling-front is not often used, because portrait lenses seldom give good definition in the margins, and cameras rarely allow enough drop, even if the lens permitted of this movement being employed.

Now it can be seen quite plainly that with a camera placed as described the head of the sitter will be nearer the lens than the lower part of the subject, whether it be the feet in a full-length, or the breast in a "head-and-shoulders" portrait. As previously stated, the image of the head will be rendered sharp on the ground-glass when the latter is further from the lens than it is when the other part is sharply focussed. If therefore the top of the focussing-screen is swung slightly towards the lens, it will be found possible to get (by a little trial and error in adjusting the swing-back and the focussing pinion) both parts of the image sharp without stopping down at all. Similarly, if one shoulder is turned away from the camera, a side-swing can be used to get both shoulders sharp at the same time. For that reason most studio cameras as provided with a side-swing, but stand-cameras rarely are.

In the latter, the movement is seldom called for, except for photographing a receding row of houses or a railway train, etc. Sometimes a little slackness in the camera parts allows of a certain amount of side-swing, or, if not, it can generally be temporarily introduced if required in an emergency by loosening a few screws. The rule is, that the ground-glass is nearer the lens for the distant part of the subject, so that once the principle is understood it will be sufficient to swing the back parallel (or thereabouts) with the subject itself, and then little adjustment will be required beyond this to get all the details sharp at a large aperture.

It requires to be impressed on the student that it is only points that lie in one plane that can be obtained sharp in this way. For instance, the swing-back is frequently employed to get the different rows of heads in a large group sharp when the light is not bright enough to allow of much stopping-down. In this case the plane focussed on is the one in which all the heads lie, and the feet of the front row will be a good deal out

of focus, so that in a group consisting of several rows it is not advisable to have any figures seated on the ground among the feet of the front row, as children are often placed, if it is proposed to swing the back and use a large aperture.

In pure landscape photography the back swung with the top away from the lens will render a large expanse sharp at a very large aperture indeed. Thus a river, crowded with boats, or other subject with much detail from quite near to extreme distance can be photographed "instantaneously."

So far I have not dealt with the swing-front, which has certain advantages over the swing-back, but also some rather strong disadvantages. In architectural work, it seems immaterial whether we first point the camera upwards and then swing the back vertical or first level the whole camera, and then point the lens itself upwards. The advantage of the latter method, which entails the use of the swing-front, is that if the image is not quite central on the focussing-screen the camera may be revolved without any readjustment of the parts being required. Another strong advantage of the swing-front is the comfortable manner in which the image can be observed while the lens is being adjusted.

The same remarks apply to the use of this movement in other branches, but the great drawback attaching to it is that swinging the lens throws the centre of the image a long way from the middle of the ground-glass and the rising or falling front has to be brought into play to correct this. In extreme cases the latter movement will be all taken up in correcting this fault, and no benefit will be obtained from it on its own account. So that unless a camera is built with an extraordinary range of movement it will be found best in the vast majority of cases to stick to the rising-front and the swing-back as the most adaptable movements. There are cases, however, where the swing-front will enable one to do what would otherwise be impossible. Take, for example, a large group as previously mentioned. In a dull light the swing-back brings the various rows of heads into sharp focus without stopping down. But supposing the group is posed in front of a building. The suggested use of the swing-back would distort the vertical lines violently, so that if the back is fixed vertically to keep the lines of the building true, and we swing the lens slightly upwards, we can still get the same apparent depth of focus in the faces which could not otherwise be obtained without considerable stopping-down.

This brings one to the matter of the lens, stops, or diaphragm. The smaller this is, in proportion to the camera extension, the longer the exposure required. This has been scientifically worked out into a series of proportionate sizes which are marked on the mounts of all modern lenses in such a way that the exposure for each can be accurately determined. These apertures are such that each requires exactly double the exposure of the next larger one, and for a fuller understanding I would refer the reader to the instructions for use of any good exposure meter, without which no outfit is really complete.

D. CHARLES.

GREEN'S ELECTRIC RETOUCHING PENCIL.—We are asked by the Lightning Retoucher Company, Stebbins Block, Michigan, U.S.A., to point out that there are no restrictions on the shipping of this

speciality from America, as these goods are not regarded by the Department of Import Restrictions in this country as coming within the scope of the prohibition of imports at present in force.

HOW TO PREPARE PHOTOGRAPHIC SOLUTIONS.

[The following paper, contributed by Mr. J. I. Crabtree, of the Eastman Research Laboratory, to the "Motion Picture News," contains so much in the way of plainly-expressed instruction on the compounding of the commonly used photographic solutions that we venture to say there is not a single photographer who will not get some practical hints from it. In reprinting it as it stands it is necessary that we should make clear the difference which exists between the measures of volume used in this country and in the United States. Mr. Crabtree, in addressing himself to American workers, refers only to the measures used in the United States; but it requires to be pointed out that the American pint and the American gallon are different from the measures of volume employed under the same name in Great Britain and in many parts of the British Empire. The U.S. pint is one of only 16 ounces, equal approximately to 500 c.c.s.; and the U.S. gallon is, therefore, one of only 128 ounces, equal approximately to 4,000 c.c.s. On the other hand, the Imperial pint, as the British standard is called, contains 20 ounces, equal approximately to 600 c.c.s.; whilst the Imperial gallon contains 160 ounces, equal approximately to 5,000 c.c.s. The ounce is the same in both systems, and there is no difference in the avoirdupois weights commonly used in this country and America.—Eds. "B.J."]

ALTHOUGH the majority of amateur photographers prefer to purchase photographic chemicals in a condition ready for use, in the case of advanced amateurs, professional photographers and motion-picture producers who use chemicals on a large scale, it is customary for them to prepare the various photographic solutions from the component chemicals.

In order to be able to prepare correctly any and every solution used in photography a knowledge of the properties of the chemicals used and of the chemical reactions involved during the mixing is essential, though by adhering strictly to printed directions it is usually possible for an unskilled worker to prepare the developing and fixing solutions as generally used. However, instructions for the use of various materials differ, for example, in the case of some developing formulæ it is recommended to dissolve the Elon first, while according to others the sulphite should be dissolved first. Both methods may be right, but if a systematised method of mixing is followed, and especially if the photographer has a knowledge of the reactions involved, then he can proceed to mix any developing solution with confidence, and what is more, he will be able to locate the trouble if for any reason the solution does not work correctly after mixing.

In this article it is the purpose of the author to describe in as non-technical language as possible the systematised method of preparing solutions now practised in the research laboratory of the Eastman Kodak Company.

Definitions.

A solution of any kind is obtained by dissolving a solid or a liquid in another liquid (or solid). The substance being dissolved is called the *solute*, and the liquid in which it is dissolved is called the *solvent*. The extent to which the solute is soluble in the solvent is called its solubility, and when the solvent will hold no more of the solute it is said to be *saturated*.

The degree of solubility of any chemical depends on the nature of the solvent and on the temperature, which should always be stated.

If a saturated solution is cooled down to a lower temperature, crystals usually form which settle out until the saturation point is reached at that particular temperature, though in the case of a substance like hypo, if all dust is excluded, crystals do not separate out on cooling, and a so-called *super-saturated* solution is obtained. However, if a small crystal of hypo is added to the solution, crystals immediately form and continue to grow until the saturation point is reached. The best method of preparing a saturated solution therefore is to dissolve the chemical in hot water, cool to room temperature with shaking, allow to stand, and filter.

Meaning of "Water To."

When a chemical is dissolved in water the volume of the solution is usually greater than that of the water used, because the particles or molecules of the chemical occupy a certain space when in solution. In case two liquids are mixed, the final volume of the liquid is not necessarily equal to the sum of the volumes of the liquids mixed, it may be greater or it may be

less. Thus fifty volumes of alcohol when added to fifty volumes of water at 70° F., produce ninety-seven volumes of the mixture and not one hundred. Moreover, equal weights of different chemicals do not occupy the same volume.

In photography we are concerned only with the weight or volume of each chemical in a fixed volume of the solution, so that when mixing, the chemical should be dissolved in an amount of water appreciably less than that called for in the formula, and then water added up to the amount stated.

The Metric System of Weights and Measures.

In photographic practice, *solids* are weighed and *liquids* are measured either by the metric or the avoirdupois system.

Although a large majority of photographers use the avoirdupois system of weights and measures, this system is inconvenient and complicated as compared with the metric system.

The metric unit of length is the *metre* (which means measure). The metre is divided into one hundred parts called *centimetres* or *cms.*

The unit of volume is the cubic *centimetre*, written *cc.*, or *ccs.* in the plural, 1,000 *ccs.* being equal to one *litre* or 1 L. The cubic centimetre is sometimes termed a *millilitre* or *ml.* (meaning one-thousandth part of a litre) though the term *cc.* is satisfactory for photographic purposes.

The unit of weight is the *gramme* which is the weight of 1 *cc.* of water at 4° C., at which temperature a given volume of water weighs the most. The gram is written *Gm.* for short, the capital letter *G* being used so as to differentiate between *Gms.* (grammes) and *grs.* (grains).

For compounding photographic formulæ only *Gms.*, *ccs.*, and *litres* are used, and fractions are always expressed as a decimal just as in the case of the U.S. currency which is a metric currency. The beginner should therefore think of grammes and parts of a gramme as if they were dollars and cents. Thus, 535 *Gms.* corresponds to \$535 or \$535/100.

The Avoirdupois System.

In photography the following table is used:

Weight.		Volume.	
437 grains	= 1 ounce ...	60 minims	= 1 fluid drachm
16 drachms	= 1 ounce ...	8 fluid drachms	= 1 fluid ounce
16 ounces	= 1 pound...	480 minims	= 1 fluid ounce
		16 ounces	= 1 pint ¹
		128 ounces	= 1 gallon

The Conversion of Formulæ.

Every photographer should be able to convert a formula given in avoirdupois terms into metric equivalents without reference to a table. It is simply necessary to remember that—

15 grains =	1 Gm.
1 ounce =	30 Gms.
1 fluid ounce =	30 ccs.
1 gallon =	4 litres ²

⁽¹⁾ The Author is here speaking of the American pint of 16 ounces equal approximately to 500 ccs.

⁽²⁾ The author here refers to the American gallon of 128 ounces. The English (Imperial) gallon contains 160 ounces equal approximately to 5,000 ccs.

from which it is readily deduced that—

2 pounds (roughly)	=	1 kilogram
1 ounce "	=	450 grs.
1 pint "	=	500 ccs.
1 cc. "	=	50 minims

The foregoing conversion figures are not strictly correct, for example one gramme=15,432 grs., 1oz.=28.35 Gms. and 1 fluid oz. = 29.43 ccs. In taking 1 Gm. as an equal to 15 grs. we are making an error of four parts in 154, or nearly 3 per cent., but in photography on error of 5 per cent. in most cases is permissible. Thus if a formula called for 453½ grs., if this were cut to an even 450, the difference would not be detectable by photographic means, though if a quantity of 6½ grains were cut to 5 grs. then the error (20 per cent.) would be serious.

Uniformity in Formulæ.

Formulæ should always be given in both metric and avoirdupois equivalents, but in some cases the proportions are given for, say, 40 oz., in one case and 1 litre in the other. Now 40 oz. = 1,200 ccs., so that the several quantities are not equivalent. This leads to error in case the chemicals are weighed out with avoirdupois weights, and the solution made up to strength in a litre graduate, though if these quantities are given for 32 oz. of solution which are equivalent to 960 ccs., or roughly 1 litre, no serious trouble will arise if the above mistake is made.

The order in which the ingredients are given in the formulæ is of importance. In some cases water is placed first, in other cases last, but since all developers are mixed with water, its position should be last in the formula. The ingredients should be given in the order in which they are dissolved, which is as follows: (1) preservative; (2) developing agent; (3) accelerator; (4) restrainer; (5) water to.

Percentage Solutions.

In photography two kinds of solutions are used as follows:

- A solid in a liquid.
- A liquid in a liquid.

(a) The misunderstandings which have arisen from time to time regarding the correct method of preparing solutions of a definite percentage strength is due to the fact that there are three ways of doing it. For example, we can make a 5 per cent. solution of potassium bromide as follows:

- Dissolve 5 Gms. in 100 ccs. of water.
- Dissolve 5 Gms. in 95 Gms. of water making 100 Gms. of solution.
- Dissolve 5 Gms. in a little water, and make up to 100 ccs.

In case (1) we have about 103 ccs. of solution, and in case (2) about 98 ccs. A chemist would use method (2), but method (3) is used when preparing photographic solutions. Method (1) is not used for the reason given above, namely, that equal weights of different chemicals do not occupy the same volume.

The percentage strength of a solution therefore merely indicates how much of the chemical is dissolved in 100 ccs. of the solution.

To prepare a 7 per cent. solution of potassium bromide, therefore, take 7 Gms. of the salt, dissolve it in a little water, and add water up to 100 ccs. If we now measure out 100 ccs. of the solution we have measured 7 Gms. of the solid.

In the avoirdupois system a 10 per cent. solution of solid is made by taking 1 oz., and making up to 10 oz. with water. Converting these figures into Gms. and ccs. we have 30 Gms. in 300 ccs., or a 10 per cent. solution.

Strictly speaking, this is not correct, since 1 oz. = 28.35 Gms., and 1 fluid oz. = 29.57 cc., so that 1 oz. in 10 fluid ozs. is equivalent to 28.35 Gms. in 295.7 cc. or 9.6 Gms. in 100. The error involved, however, is less than 5 per cent., and for ordinary purposes is therefore negligible.

If a photographic solution is made by any of the above methods, 1, 2, or 3, the error involved is less than 5 per cent., and therefore negligible for ordinary photographic purposes,

though since the correct method is the easiest, it should be followed.

Although somewhat of an anomaly, it is possible to prepare a 100 per cent. solution of a substance like hypo by dissolving 100 Gms. (which do not occupy a space of 100 ccs.) and dissolving in sufficient water to make 100 ccs. of solution.

(b) A 10 per cent. solution of a liquid in water is made by taking 10 cc. of the liquid and adding water up to 100 cc.

The Meaning of "Parts."

It is often recommended to dissolve, say, 10 parts of a solid in 100 parts of water. Such a statement is meaningless because a solid chemical is weighed while a liquid is measured, though if the metric system is used, since 1 cc. of water weighs 1 Gm., then grams and ccs. may be considered synonymous with parts.

In the case of liquids, parts should be taken as meaning units of volume, and in the case of solids as units of weight. A "part" may therefore mean anything from a gramme to a ton, or a cc. to a gallon so long as the other quantities are reckoned in the same units of weight or volume.

Thus:

For use: A three parts	A 300 ccs.	A 15 oz.
	may mean	or
B one part	B 100 ccs.	B 5 oz.

If the avoirdupois system is used and the formula contains both solids and liquids, if ounces (liquid) and ounces (solid) are substituted for "parts," the error involved falls within permissible limits.

Problem.—Mix one gallon (U.S. of 128 oz.) of solution, according to the following formula:—

Sodium sulphite	10 parts
Pyro	1 part
Water to	100 parts

Now, one gallon equals 4,000 ccs. Therefore, dissolve 400 Gms. of sulphite in water, add 40 Gms. of pyro, and make up to 1 gallon.

"Drops."

If a formula calls for, say, 5 drops of a solution, this is a very uncertain quantity because drops of liquid vary considerably in size. The average drop from the usual dropping bottle or burette measures about 1 minim or a little less than one-tenth part of a cc., so that 5 drops may be considered as 1/3 cc. or 5 minims.

The Hydrometer Test.

Many photographers are accustomed to making up their stock solutions of hypo, carbonate, sulphite, etc., by means of the hydrometer. This method has the advantage that in case the hypo (say) has become moist and contains an unknown amount of water, a definite reading on the hydrometer will give a solution of the same strength as if perfectly dry chemicals had been used. When a stock solution is made from moist chemicals by weighing, the error caused by the presence of water may be as high as 25 per cent. or 50 per cent.

The hydrometer method has the disadvantage that the adjustment of a solution to the required strength takes considerable time, the hydrometer reading does not convey an idea as to the percentage strength of the solution, while the hydrometer reading varies with the temperature. For instance, if a stock solution is made with hot water and this registers, say, 45 on the hydrometer, on cooling, the liquid may register 48 or 50. It is therefore absolutely necessary either to make all readings when the solutions have cooled to room temperature, or to prepare a table giving the variation of density of each solution with temperature.

Usefulness of Per Cent. Solutions.

The great advantage of stating the strength of any solution in parts per hundred is that a definite mental picture is at once created of its relative strength, while by means of a number of stock solutions it is possible to compound certain formulæ by

simply measuring out a definite volume of each solution thus dispensing with a balance. Thus, supposing we have a 10 per cent. solution of potassium ferricyanide and of potassium bromide already at hand, and it is desired to make up the following solution:—

Potassium ferricyanide	6 Gms.
Potassium bromide	2.3 Gms.
Water to	1,000 ccs.

then it is only necessary to measure out 60 ccs. of the ferricyanide solution, 23 ccs. of the bromide solution and add water up to 1,000 ccs. and the solution is made.

In the case of very concentrated solutions it is not always possible to use this method, though in view of the time saved, and the accuracy of the method, it should be applied whenever possible.

Suppose a formula calls for 0.1 Gms., it is impossible to weigh this amount accurately on the usual photographic scale, but by measuring out 1 cc. of a 10 per cent. solution, and adding this to the mixture, the problem is solved.

Photographic Arithmetic.

It is often required to mix up a quantity of solution much greater than that given by the formula, in which case the photographer must perform a very simple exercise in arithmetic in order to secure the desired result. The two following examples indicate the method of solution of such simple problems.

A. Mix 6 oz. of solution according to the following formula:

Potassium ferricyanide	4 Gms.
Hypo	10 Gms.
Water to	100 ccs.

now 6 oz. = $6 \times 30 = 180$ ccs. Therefore, we need $180/100 \times 4 = 7.2$ Gms. of ferricyanide and $180/100 \times 10 = 18$ Gms. of hypo. Dissolve these in a little water and make up to 180 ccs.

B. How would you mix 1 pint of a 7 per cent. solution of sodium sulphite?

To make 100 ccs. of a 7 per cent. solution we need 7 Gms. Therefore, to make 1 pint (500 ccs.) we need $5 \times 7 = 35$ Gms. To prepare the solution therefore, dissolve 35 Gms. of sulphite in water and make up to 1 pint (16 oz.).

Dilution of Liquids.

It is often required to reduce the percentage strength of a solution. For example: How would you mix two gallons (U.S.) of 28 per cent. acetic acid, from a supply of glacial acetic acid?

To make 100 ccs. of 28 per cent. acid we need 28 ccs. of glacial acid.

To make 1 cc. of 28 per cent. acid we need $28/100$ ccs. of glacial acid.

To make 8,000 ccs. of 28 per cent. acid we need $28 \times 80 = 2,240$ ccs. of glacial acid.

Therefore take 2,240 ccs. of glacial acid and add water to make 2 gallons (i.e. 256 oz.).

To dilute a solution three times we do not add three times the amount of water, but twice the amount, and so on. For example: One volume of solution plus 2 volumes of water = 3 volumes of solution, which is three times as weak, or three times as dilute as the original.

Stock Solutions.

A stock solution is a concentrated solution to which water is added before use. In the case of simple solutions containing only one salt such as potassium bromide, sodium carbonate, etc., a 10 per cent. solution is most convenient because by multiplying the volume of the solution in ccs. by 10 we get the number of grams present in the solution. Thus 75 ccs of 10 per cent. potassium bromide contain 7.5 Gms.

The limiting strength of solution which it is possible to make in any particular case depends on the solubility of the chemical, and as the solubility diminishes with temperature a solution should not be made stronger than a saturated solution at 40° F.,

otherwise in cold weather the substance would crystallise out. (The reader is referred to tables of solubilities given in most handbooks.)

A stock solution of sodium sulphite should be made as strong as possible (15 per cent. of the desiccated salt) because at such a strength the solution oxidises very slowly, and will therefore keep, whereas in weaker solution it combines with the oxygen in the air very readily, and is then useless as a preservative.

Apparatus.

Scales.—For quantities up to 100 Gms. a double pan balance should be used, and a larger one for quantities up to 1,000 Gms. For still larger quantities a platform scale weighing in pounds may be used, because large metric scales are not readily procurable. For preparing small amounts of sample developers a small chemical balance weighing in hundredth parts of a gramme is necessary.

Mixing Vessels.—For small quantities of solution conical glass flasks are the most suitable. For larger quantities use enamelled buckets. Earthenware crocks are usually unsatisfactory, because when the glaze cracks, the solutions penetrate within the pores, and thus contaminate any other solutions subsequently mixed in it.

A wooden stick or paddle is the best form of stirrer, but a separate one should be used for each solution so as to eliminate the possibility of contamination.

The paddle may also be used to measure out a definite volume of solution in a tank or crock by cutting notches in the paddle to correspond with definite volumes when held vertically. Such markings are only applicable, however, to the particular tank or crock for which the paddle was graduated, so that a separate paddle should be used for each tank or crock unless they are of the same shape and capacity.

Chemicals should be weighed out and the solutions prepared in a separate room, and care should be taken when handling such substances as hydroquinone, resublimed pyro, potassium ferricyanide, etc., not to shake the finer particles into the air, otherwise they will enter the ventilating system and settle out on benches, negatives, and prints, and cause no end of trouble in the way of spots and stains.

Weighing and Measuring.

Weigh out chemicals on pieces of paper, and after transferring to the mixing vessel do not shake the paper, but drop it into the sink and allow water to flow over it, thus dissolving the dust. Larger quantities are most conveniently weighed out in buckets.

For small quantities a glass graduate marked off in ccs. or ounces should be used, for larger quantities use a bucket previously graduated, or mark off the inside of the tank or crock used for mixing. When measuring a liquid in a glass graduate place the eye on a level with the graduation mark, and pour in the liquid until its lower surface coincides with this level. Owing to capillary attraction the liquid in contact with the walls of the graduate is drawn up the sides so that on viewing sideways it appears as if the liquid has two surfaces. All readings should be made from the lower surface and at room temperature because a warm liquid contracts on cooling.

Dissolving

The rapidity with which a substance dissolves in any solvent depends on its solubility and degree of fineness, the temperature of the solvent, and the rate of stirring. Since a chemical is usually more soluble in hot water than in cold the quickest way of mixing a solution is to powder it up and dissolve in hot water with stirring. In the case of a few substances like common salt which are only slightly more soluble in hot than in cold water, the use of hot water is of no advantage.

Since most solutions are intended for use at ordinary temperatures, if hot water is used for dissolving, the solution must

be cooled off again if it is required for immediate use, though usually the time taken to do this is less than the extra time which would be taken up in dissolving the chemical in cold water. When mixing, therefore, as a general rule dissolve the chemical in as small an amount of hot water as possible, cool off, and dilute with cold water.

After diluting with water, thoroughly shake the solution if in a bottle, or stir if in a tank, otherwise the water added will simply float on top of the heavier solution.

When mixing a solution in a tank, never add the dry chemicals to the tank, but always make sure that the chemicals are

dissolved by mixing in separate buckets and filtering into the tank.

If the water supply is not sufficiently cold, so that on diluting the hot solution the final liquid is not at the required temperature, the hot solution should be cooled by means of ice placed in a cloth bag to filter out the dirt.

In the case of anhydrous (dry) salts such as desiccated sodium carbonate, sodium sulphite, etc., always add the chemical to the water and not vice versa, otherwise a hard cake will form which will dissolve only with difficulty.

J. I. CRABTREE.

(To be continued.)

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).
The Postcard Studio (March 14).
The Printing-Room (March 21).
About the Reception Room (March 28).

Home Portraiture (April 4).
Portable Studios (April 11).
Copying (April 18).
Handling the Studio Camera (April 25).
More About Lenses (May 2).
Enlargements (May 9).
Advertising the Studio (May 16).
Mounts and Mounting (May 23).
Business Methods (May 30).
Photographing Children (June 6).
Portraits of Elderly People (June 13).
Something about Lenses (June 20).

HAND CAMERAS FOR PROFESSIONALS.

WHILE there is a large class of professionals, those who are almost exclusively engaged in Press photography, who use hand-cameras for the great bulk of their work, the majority look somewhat askance on this type of instrument, and are rather inclined to think it fit only for amateur snap-shots and judge its capabilities from the plates and films which from time to time are handed to them for development and printing. Judging from such material I can quite sympathise with those who regard hand-cameras as toys, but it must be borne in mind that the large proportion of failures are due, not so much to the shortcomings of the instrument; but to the inexperience of the user; and the skilled photographer will find that with a little study he can produce a very large proportion of successful negatives under conditions in which it would be difficult, if not impossible, to use a stand camera.

The selection of an instrument which will be really serviceable demands a considerable amount of care, and due consideration must be given to the class of work which will most likely be undertaken; therefore, I would counsel anyone who has not been accustomed to hand-cameras to get a little preliminary practice with a simple inexpensive article which he can supersede by a better one as soon as he has become fully conversant with its handling and has realised its shortcomings. I say this because I have known more than one who has purchased an expensive half-plate reflex and been bitterly disappointed with the work he has been able to get out of it, not because of any inherent fault in the instrument, but owing to its unsuitability for his purpose.

Although there are scores, perhaps hundreds, of different makes of hand-cameras upon the market, there are only a few well defined types, which are issued under various names by the makers. I will, therefore, give a brief description of such as I consider useful, indicating their strong and weak points, but before doing so it may be well to point out that

a hand-camera is often at its best when fixed upon a stand, just as a celebrated author pointed out that he was never quite satisfied with his fountain pen until he discovered that it was a very good ordinary pen when he dipped it in the inkstand. This leads me to what I may call the intermediate class or "hand and stand" cameras, of which we may take the small "Sandersons" as the best known example. These closely follow the lines of the ordinary conical bellows field camera, but possess the advantage of having the lens and shutter so fitted that they need not be removed from the front when the instrument is closed, while there are no openings in the body to admit dust or moisture. Focussing is normally effected by scale, but a ground glass is provided so that until the user has attained some skill in judging distances, he can focus in the ordinary way upon near objects. A finder of the usual reflecting type is fitted, and this is sometimes supplemented by a direct vision finder which allows the camera to be used at the level of the eye as well as from somewhere near the waist line. I greatly favour this type for rapidly moving objects, as the object can be kept in view before it enters the field of the finder, and, moreover, it comes into the finder on the same side instead of the opposite one, as it does in the reflecting pattern.

Such cameras are usually provided with an effective rising front, and in most cases a vertical swing to the back. The swinging front of the Sanderson, of course, answers the same purpose, so that architectural and similar difficult subjects can be tackled with the same ease as with an ordinary stand camera. Other patterns of this type are the Sinclair Una, Ross's Keros, and Watson's Alpha. Many other makers issue a somewhat similar model on quarter-plate and smaller sizes, but for professional work I am inclined to recommend the half-plate as being the most generally useful.

Of hand-cameras pure and simple the collapsible pattern best known in pre-war times as the Goerz Anschütz is un-

doubtedly the best. A similar camera of British make is the Panos, and doubtless other makers will put this pattern on the market as soon as normal conditions of manufacture prevail. The body is extended to the infinity focus of the lens by a single motion, but near objects may be focussed by means of a spiral adjustment to the lens mount. The shutter is a focal-plane one, which will give very quick exposures with the maximum efficiency as well as longer ones, say 1-10 sec., while for stand work time exposures may be made either with the shutter or cap, the latter being perhaps the more certain, as even the best focal plane shutters are apt to give a slight shock on opening. When closed these cameras are very compact and generally stand rather rough usage very well. They have no swing back, but have, as a rule, both rising and cross fronts. Press work generally, postcard views, and occasionally home portraiture come within their scope. As the bellows is of a fixed length they cannot be used with wide angle lenses, and if telephoto or other long focus lenses are to be employed, the only way of doing so is by means of an extension body, which is rather a clumsy device. However, the camera used with its normal lens is one of the most useful which a photographer can possess.

The next to claim our attention is a totally different type, which can lay no claims to portability in any except the quarter-plate size. It is the reflex in which the image is received upon a mirror placed at an angle and diverted to a focussing screen on the top of the body, while the plate is protected by the focal plane shutter at the back. On pressing the release the mirror springs out of the way and the shutter is at the same time released. The strong point of this construction is that very accurate focussing can be done at large apertures, hence it is useful for all classes of natural history work, child studies, and home portraiture. It is little used for Press work on account of its bulk and the fact that it cannot be conveniently used at the level of the eye. There are several models of folding body reflex cameras which are less bulky to carry, but they are more likely to get out of adjustment than the box form, and I do not recommend them for professional use.

An older type of reflex is known as the twin-lens camera. In this the mirror is a fixture and the body is divided into two sections, each fitted with an identically similar lens, the upper being used for focussing only while the lower is provided with a shutter for exposing. In some respects they are superior to the single-lens reflex as the image is visible the whole time, and there is no interval between the pressing of the release and the movement of the shutter, but their still greater bulk and the expense of a second lens has caused them to go out of fashion. It may be said that a cheaper lens could be used for the focussing finder, but after many experiments I was forced to the conclusion that to get the best results the two lenses must be identical in construction. Another failing is that with near objects there is a discrepancy between the view in the finder and that upon the plate, that is if the adjustment has originally been made for infinity.

Kodaks are generally regarded as purely amateur cameras, but when skillfully used are capable of really good work. The cheaper grades are naturally limited in their scope by the slowness of the lenses with which they are fitted, instantaneous exposures at $f/8$ even being only possible in a good light. When supplied with rapid anastigmats much greater possibilities are opened up, and the photographer who wishes to carry a hand camera which needs the minimum of space will

do well to give the Kodak a trial. The 3a or postcard size will be found the most useful. In this connection I must not forget that British-made cameras of this pattern are issued by Messrs. Houghton and Butcher and Sons, under the name of Ensign and Carbine respectively, also fitted with anastigmat lenses.

Very small cameras of the Blocknote and Vest-pocket types possess but little interest for professional workers, although the late Mr. Essenghigh Corke has recorded in these pages how they have stood him in good stead when larger instruments were impossible, but as a general rule too great a degree of enlargement is necessary for them to be generally useful, as it is usually necessary for the prints issued to compete on equal terms with direct work, and with most rapid plates the grain of the emulsion precludes this.

Now a word as to lenses. A hand-camera which can only be used in the best of light is of very limited utility, therefore I would say that whenever possible a lens with a maximum aperture of $f/4.5$ should always be chosen if possible. It is not always necessary to work at full aperture, in fact, it is better to stop down as much as it is safe to do, but there are times when the large aperture is badly wanted, when it turns thoroughly dull just as the Royal or noble party arrives at the fete, or when the conclusion of the sports is deferred and the best of the light is gone; then is the time when the 4.5 lens begins to earn money. Of late years fixed focus telephoto lenses of large aperture such as the Telecentric and the large Adons have come on the market, and these will often be found useful for cricket matches, sports and the like. It is necessary with these on account of their focal length to focus very accurately so that they should only be used upon reflex cameras or those fitted with a focussing screen, scale focussing with say a 16 in. lens being very difficult, if not impossible.

It is wise to provide oneself with a light stand for slow instantaneous exposures; few people can keep a camera absolutely steady for a tenth of a second, and fewer still for a fifth, yet there are many subjects which are only possible with such exposures, and they are rendered easy if a stand is available. It may be thought that there is no time to use it, but if the camera is fitted with a direct vision finder, the whole affair can be dropped down and the exposure made in two or three seconds.

As the exposures in hand-camera work will in many cases be on the side of insufficiency, every precaution must be taken to make the best of them, that is to say, that the most rapid plates should be selected, that they should be quite fresh and that every precaution should be taken against fog in the dark room. Development will also be somewhat different from that of fully timed exposures. There is always a tendency to over-develop under-exposed plates and this only results in the high-lights becoming too dense without any addition to the shadow detail. It is a good plan to use a developer diluted to half its usual strength and to develop only a little longer than for ordinary exposures, this will give a rather thin negative which will print very well upon a suitable paper, but which may be intensified if necessary. If this be done the shadow detail will also gain in density which is not the case if full density be obtained by development. Another useful tip is to use backed plates; one never knows what position the subject will happen to take, and if it happens to be against the light a failure is certain with unbacked plates, for extra rapid emulsions are very transparent and allow much light to pass through. PRACTICAL.

THE WAR SAVINGS ASSOCIATION in connection with the firm of Rajar, Ltd., Moberley, have collected £8,228 11s. in Certificates and Bonds up to the end of March, 1919, with an average membership of 115.

MR. A. S. RAY is now calling on all photographers in Great Britain in the interests of Monomet and other photographic chemicals manufactured by the White Band Manufacturing Co., Ltd.

SILVERING MIRRORS.

APART from its usefulness, silvering glass is a most fascinating process. There are numerous formulæ, and I have tried most of them. Nothing in my trials gives the highly brilliant deposit that sugar does. I take

Castor sugar 1 lb.
Tartaric acid 1 oz.

put into an enamelled eaucepan, and just cover with rain or distilled water. Bring to the boil; when cool, make up to 60 ozs. solution and add 5 ozs. alcohol, the more rectified the better. This and subsequent solutions keep indefinitely, but should not be used fresh. Now take a 5 per cent. nitrate silver solution which has been precipitated with ammonia, and just cleared. Of this, use, say, 2 ozs.; precipitate again with some caustic soda or potash solution of 10 per cent. (about $\frac{1}{2}$ to 1 dram is sufficient); just clear again with ammonia, and add $\frac{1}{3}$ of its bulk of the following:—

Sugar stock solution 1 oz.
Rain or distilled water 10 ozs.

This should be added just at time of silvering the glass, which takes two to three minutes in a temperature of 80°. If the first application does not give density enough, a second can immediately be given by pouring off the old one and applying the fresh one. This gives a beautiful, highly-polished film, and is tenacious. There is no need of the tremendous purity of chemicals one sees insisted upon. Mr. Crowther's article in a previous "B.J." is similar to the above. A variety is to add 10 drops of 40 per cent. formaline to the stock sugar solution. This gives a tremendously thick silver without bloom, and is perhaps more advantageous than using formaline alone. In using formaline alone it is surprising what a small amount is required. 10 minims in 10 ozs. water is usually sufficient; this, however, does not work so smoothly or brilliantly as sugar.

In cleaning the glass, a 10 per cent. solution of tin chloride is the most useful to use, giving the glass a "bite" and getting rid of all grease. I have used this solution for years for other purposes, and find it excellent.

Rochelle salts as a depositing agent, unless pure, is not so satisfactory, and takes a long time to deposit. The most messy formula is that of oil of cassia and clove. I did not find methyl violet dye, as given in a recent formula, of much advantage, tending to discolour the silver; also there is no advantage in retarding the deposit. Excessive alcohol gives films rather transparent and of a violet colour when looked through. In a temperature of 80°, silvering of glass is absurdly simple.

W. W. WALL (Ceylon).

Photo-Mechanical Notes.

Why Do Engravers Use Wet Collodion?

Wet collodion is a beautiful process, but so it always was, and yet it has been displaced by dry plates in every department of photography except photo engraving. How is this?

The engravers will perhaps say that the results are better, but do they not deceive themselves? Results equal to wet plate can be produced on suitable process dry plates, though the negatives themselves may not look quite so attractive. But then the negative is not the end itself, as the operator so often appears to think, but a means to the end. Much difficult copy that is impossible to wet collodion is easy to dry plate.

It is sometimes said that wet collodion is cheaper. This also is very doubtful if account is taken of all the expenses in connection with collodion, the glass always much larger than the picture, the preparation of the plates, the time taken in preparation, the extra chemicals, the extra space required, the extra wear and tear of apparatus due to the use of corrosive material, the extra fire risk on account of the inflammable nature of collodion, etc.

Again, it may be said that collodion is quicker. If this is so, the Press photographer's attention should be called to it, and it is remarkable that the military authorities did not turn to it—with dry-plates our air force photographers managed to develop their exposures and deliver prints in an incredibly short time. Joking

aside, it is possible the wet-plate man can make a record speed if you give him a plate ready for exposure, but if you include the time taken to first clean the glass, coat it, sensitise it, then add the extra time necessary for exposure, the wet plate will be hopelessly slower. Moreover, wet plates must be separately and individually handled throughout, whereas dry plates can be handled in batches, which is a tremendous economy of time if one has sufficient work to do.

Many methods have been devised or suggested for systematising exposure. Why not carry this a step further and use a material that would enable development and printing to be systematised also? While the writer is firmly of opinion that ultimately dry plates will displace wet collodion, there seems small prospect of it at present, and he is like most other engravers everywhere, using wet collodion except for difficult work that wet collodion will not do—when he has to turn to dry plates.

Engravers are conservative craftsmen, and not until they begin to make exposures direct on metal in the camera (which they will be forced to do sooner or later, probably by the photo-lithographers, and because customers insist on more and more speed), will they give up their beloved messy old silver bath, and take to a ready-prepared sensitive material. Then, although they will be getting results better than ever, they will still regretfully refer to the "good old days" when quality that has since disappeared was always found because wet collodion was in vogue.

Standardising the Etching Time.

A want of uniformity is one of the most undesirable characteristics of all photo-mechanical operations, and nowhere is this want of uniformity more apparent than in the etching department. With a uniform negative a definite time in the etching bath should give uniform tone and uniform depth of etching. This assumes, however, that the conditions of etching are standard, that the manner of etching is kept the same, whether face up or face down, bath-rocked or still; that the temperature of the etching solution is kept even, and that the strength of the etching solution is uniform. This latter point, perhaps, presents the most difficulty because the strength varies according to the amount of metal etched. It is probable that a good plan would be to take a certain quantity of solution at a certain hydrometer strength and allow so many square inches to be etched all at the same time in such a bath and then throw it away. Of course, this is not very easy to arrange in the average photo-engraving shop, where each job is wanted at once and many have to be done individually. A plan that has been adopted, which, we are told, works with tolerable success, is to make up the bath of perchloride of iron to 34 degrees Baumé. At the beginning of every day about one-fifth of the bath is removed and replaced with fresh solution at 40 degrees, the bath tested and diluted with water if it registers more than 34 degrees. Unless there is some use for the spent solution, this may seem a little extravagant, but it is worth it, for the certainty that a plate left in the bath so long will be sure to be etched as much one day as another.

Exhibitions.

PHOTOGRAPHS BY N. E. LUBOSHEZ.

THERE is now on view at the Royal Photographic Society a one-man exhibition of photographic portraits by Mr. N. E. Luboshez, the object of which is to show the possibilities of pure straightforward photography. Most of the examples shown were taken in front of audiences during demonstrations on lighting at various photographic conventions. Some were taken in ordinary rooms, and a few were taken in studios of well-known photographers to demonstrate either flashlight or some particular form of electric light. The exhibits show in a very striking manner the possibilities that are open to any photographer who thoroughly understands his medium. It should be noted that neither the negatives nor the enlargements have been touched up in any way. They are absolutely straight enlargements from straight negatives. The exhibition opened on June 23, and will close on Saturday, July 12. Admission is free on presentation of visiting card.

Patent News.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

MAGNESIUM LAMP.—No. 120,736 (May 15, 1919). This invention relates to a magnesium lamp for photographic use, and in which, for ignition of the light-producing powder, is used an ordinary match, which is struck against suitable striking composition.

The characteristic features of the invention consist in the placing and displacement or turning of the match; while all the other parts of the mechanism may be varied in many different ways.

In the drawings,

Figure 1 shows a form of lamp in side view ready for use.

Figure 2 is a detail of the match holder.

Fig. 5.

Fig. 1.

Fig. 4.

Figure 3 shows the lamp in plan view.
Figure 4 is a side elevation of another form of construction of the lamp.

Figure 5 is a perspective view of the arrangement of the match-holder on the mechanism.

Figure 6 illustrates the placing of the match in the striking composition.

The lamp itself consists of a plate 1, which is horizontal when

in working position, with a bent rear edge 2, upon which the back plate 3, which is vertical when in working position, is fixedly mounted and kept fast in the open position by a pair of leaf-springs 4.

The front part 5 of the plate 1 is stepped upward and provided with an upstanding outer edge 6. In the middle of the member 5 is stamped out a tongue 7, which is below the level of the

Fig. 3.

member 5, so that by this tongue and the surrounding edges of the member 5 there is formed a holder, which may be of a yielding character.

On the underside of the plate 1 there is arranged near the rear edge 2 a hoop 8 for receiving the end of limb 15 of the handle 14-15 and across the upper side of the plate lies a match-holder 9, which, in the form of construction now being described, is square, and so arranged that it may pass through a corresponding hole in the rear edge 2. The holder 9 has a through hole 10, so that the device may be cleaned, and carries a screw 11. The rear end of the holder 9 has a cylindrical neck 12 and a head 13 of rectangular form.

The handle consists of a V-spring, the two limbs of which are designated 14 and 15 respectively. The upper part of the branch 15 has a bend 16, which engages with a slot, formed by the limb 14, after which the end of the bend 16 is bent up at 24, while the outer end is arranged to co-operate with the hoop 8, so that the plate 1 may set fast on the handle. As an alternative it is obvious that the portion 24 of the limb 14 might co-operate with a hoop attached to the back plate by giving same a slight bend to one side.

The upper end of the limb 14 is likewise bent, and forms a slot for the head 13 of the match-holder 9.

The limbs 14 and 15 may have a pair of finger plates 17 to conveniently manipulate the handle.

The apparatus acts in the following manner:—

The back plate 3 is put up, so that the holding springs 4 keep the plate in the vertical position. The holder 9 is pushed back, and the slot in the limb 14 is passed over the head 13, with the holder in the horizontal position.

When the head 13 has come behind the slot, so that the sides thereof embrace the neck 12, the holder is turned into the vertical position, and the end of the branch 16 is pushed into the hoop 8. This position is shown in Figures 1 and 3.

The bent striking composition member 18 is now placed in the clip between the tongue 7 and the plate 5, and the plain end of a match 19, which is introduced between the two pieces of the striking composition, is pushed into the match-holder 9 and is clamped fast by the screw 11. Light-producing powder is then placed on the plate 1 above and around the holder 9, and in such a manner that there is plenty of powder at the place where the match 19 leaves the hoop of the striking composition 18.

The apparatus is now ready for use, and in such a way that the limbs 14 and 15 are pressed together, or, rather, the limb 14 is pressed up against the limb 15; the head of the match 19 is drawn out of the striking composition 18, which yieldingly embraces the head, and as the match catches fire it will at the same time ignite the powder lying on the plate 1.

When the apparatus is not used, the handle 14-15 is removed,

and is, together with the match-holder 9, placed on the plate 1, after which the plate 3 is shut down. The whole apparatus takes up but little room, and is easily transportable.

Instead of the head 13 any other means of connection between the holder and the spring-branch 14 may be used.

In Figure 4 is shown a modified form of construction for the actuating of the match-holder 9, which has in this modification behind the back plate 3 a head 13, but this co-operates with a pin 20, which, by a Bowden release 21, is in connection with a press-knob 22 and corresponding handle 23, so that the pin 20 may be pushed forward, which movement is transferred to the head 13, and therefrom to the match-holder. By this arrangement the handle 14-15 is superfluous, and the lamp may then be worked at a distance, as the Bowden release may be of any length. Moreover, the lamp may be arranged to be used as well with a handle as with a Bowden release, as might be preferred, in that the Bowden release may be arranged to draw instead of to pull; its front part (the wire and the end of the spiral) may then be fastened respectively to the head 13 of the match-holder and to an elongation upwards of the handle-branch 15.—Jens Peter Hansen, Jacobs Allé 10, Copenhagen, Denmark.

Trade Names and Marks.

TRADE MARKS REMOVED FROM REGISTER.

In the official language of the "Trade Marks Journal" the following trade marks have been "removed from the register through non-payment of renewal fees." Such non-payment is, of course, the method adopted by a firm having no further occasion for the use of a mark :—

- EIDELER.—No. 270,903. Registered by R. and J. Beck, Limited, in 1905. (Class 39).
 EIDELER.—No. 270,902. Registered by R. and J. Beck, Limited, in 1905. (Class 1).
 EIDELER.—No. 270,498. Registered by R. and J. Beck, Limited, in 1905. (Class 8).
 MATTOS (DESIGN).—No. 270,712. Registered by Mattos, Limited, in 1905. (Class 39).
 MATTOS (DESIGN).—No. 270,711. Registered by Mattos, Limited, in 1905. (Class 1).
 IDENTO.—No. 270,884-85. Registered by A. L. Adams, trading as Adams and Co., in 1905. (Class 8).
 BROMIRES.—No. 271,542. Registered by the Rotary Photographic Co., Limited, in 1905. (Class 39).
 LIVING PICTURE (CAMERA DESIGN).—No. 271,675. Registered by G. H. Garner, trading as the Living Picture Series Co., in 1905. (Class 39).

APPLICATIONS FOR REGISTRATION.

- WIP.—No. 390,174. Cinematograph projectors, cinematograph cameras, and cinematograph apparatus. Thomas Edward Carnal Wheeler, 9, Cecil Court, Charing Cross Road, W.C.2., manufacturer. April 14, 1919.

REGISTRATION RENEWED.

- Poco.—No. 272,792. By Kodak, Limited, in 1905. (Class 8).

Photographic Printing on Wood.

A SIMPLE formula for printing photographs on wood from reversed negatives (says "The Process Engravers' Monthly" for June) is the following :—

The sides of the wood block are rubbed with heated wax or paraffin. This is to keep moisture from injuring the wood. Three solutions are kept in stock ready for use :—

1. Gelatine, 16 grs. to 1 oz. of water.
2. Silver nitrate, 80 grs. to 1 oz. of water.
3. Citric acid, 40 grs. to 1 oz. of water.

The white of an egg is beaten to a froth and left standing over night.

To sensitise a block, take: White of egg, 1 dram; gelatine solution, $\frac{1}{4}$ dram; best zinc white, $\frac{1}{8}$ oz.; ammonium chloride, 5 grs. Rub these to a paste in a glass mortar, and while rubbing drop slowly into the paste 30 minims of the citric acid solution and 30 minims of the silver nitrate solution. Paint this on the wood block very thinly, seeing to it that the block is completely covered. Dry quickly in the dark and print under negative as usual, timing the print so as to keep a record of what length of time is best, which will vary with different negatives and different lights. Fix the print in the dark-room by holding it face down for a few minutes in a tray of hyposulphite of soda. Wash the hypo from the face of the wood quickly and remove the moisture with damp chamois or blotter. Dry quickly. This will give a brilliant print with no film to interfere with the gravers. The wood is not injured by chemicals if care is used to wet only the surface of the block.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JUNE 28.

Hackney Photographic Society.—Annual Sports.
 Chelsea Photographic Society. Outing: Kingston to Richmond.
 Liverpool Amateur Photographic Association. Outing to Cheetham Hospital, Manchester.
 South London Photographic Society.—Excursion to Strand-on-the-Green and Kew.
 North Middlesex Photographic Society.—Ladies' Outing to Beckenham.
 Manchester Amateur Photographic Society: Outing: Bramhall to Adlington.

MONDAY, JUNE 30.

South London Photographic Society.—"Personal Practice in Pictorial Printing." E. C. Perry.

TUESDAY, JULY 1.

Manchester Amateur Photographic Society. Beginners' night, "The Equipment of the Dark Room." Messrs. Chapman, Crowther, and Pullen.

WEDNESDAY, JULY 2.

North Middlesex Photographic Society. Platinootype. A. H. Lisett.

THURSDAY, JULY 3.

Hampshire House Photographic Society. "Bromide Printing and Enlarging." M. O. Dell.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the Council was held on Friday, June 13. Present: Messrs. A. Basil, Gordon Chase, C. F. Dickinson, A. Ellis, S. H. Fry, R. Haines, Lang-Sims, R. N. Speaight, H. A. St. George, and F. G. Wakefield (London members), and Marcus Adams (Reading), T. Chidley (Chester), W. Illingworth (Northampton), and F. Read (Southport).

The minutes of the previous meeting were read and confirmed.

Letters of regret for non-attendance were received from Messrs. Alex. Corbett (London) and W. B. Chaplin (Windsor).

The Hon. Sec. reported that No. 13 of the new issue of the P.P.A. Circular had been issued to the members. As secretary he had received the full average number of letters of inquiry for the advice and assistance of the Association, and these had been duly dealt with. Amongst these inquiries was one complaining of the action of a firm who advertised photographic sundries, and from whom neither goods nor a refund of money could be obtained. The Association had now a definite promise from the firm in question, and it was hoped that the matter would be settled without recourse to legal process. (A member of the Council had had similar trouble with the same firm.) Another complaint was the not uncommon one of breakage of negatives in the post. Correspondence had followed with the Postmaster-General, who insisted that the Post Office rule, that if the outside of the package was intact and in good order, it was to be assumed that any damage to fragile goods inside (and photographic glass plates must be included in that category) was due to defective or insufficient packing, must hold good. The utmost care and the use of sufficient and suitable packing must be the antidote to the rough usage by the Post Office servants. Many other complaints of a more or less special character had been investigated, including one from a member whose fellow-townsmen was—he alleged—showing specimens in his showcase which were not produced in his own studio. As the photographer complained of was known to more than one member of the Council, the consideration of this complaint was deferred until more personal evidence could be produced at the next Council meeting.

It was further stated by a member that he believed one firm in the West End was undertaking to supply "portrait specimens" to any intending photographers who bought photographic apparatus or outfits from them. Further information was promised.

Mr. Marcus Adams presented the report of his committee (Haines, Lang-Sims, Speaight, and Wakefield) on the question of assistants. After careful consideration the following resolution was passed unanimously:—

"That this Council of the Professional Photographers' Association, believing it would be to the general advantage of professional photography that assistants should have an association of their own, urge them to form one, and are willing to provide the sum of ten pounds to a responsible committee towards the initial expense."

Mr. Wakefield informed the Council that he, with Mr. St. George (the President) and Mr. Haines, had interviewed the secretary of the London Trade Association, referred to in the last minutes, and had inspected the premises, which had been suggested as suitable for London offices of the P.P.A. He hoped soon to have a definite offer to place before the Council, which would provide both premises and clerical assistance, use of telephone, etc. The further consideration of this very important and far-reaching change was deferred until the next meeting.

Mr. Speaight briefly introduced the subject of the provision of a certificate of membership, which could be framed and displayed in photographers' places of business. This, and Mr. Illingworth's postponed proposition upon the advisability of incorporating the P.P.A., was adjourned until the next meeting on July 11.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS.

The first meeting of the newly-elected committee of the Society of Master Photographers was held at the office, 39, Blackfriars Street, Manchester, on Tuesday, June 17. A very large number of members were present from all parts of Lancashire and Cheshire, and the meeting was presided over by Mr. F. Kenworthy, the president.

The minutes of the previous meeting having been read and confirmed, the secretary's report with reference to the exhibition held at Blackpool was submitted for adoption. Reference was made to a letter that appeared in the "B.J." for week ending June 14, and signed by one describing himself as "Hopeful." There were some very strong feelings expressed regarding this writer and the uncharitable attitude he had taken up regarding the exhibition. It was, however, decided to treat the letter with the contempt it deserved, the writer not having had the courage to sign his name to the same. Financially, both the exhibition and the annual dinner have been a great success, and a small balance was left after all expenses had been paid. The result of the ballot was as follows:—Section 1 (studio work): 1st prize, Ralph Jones, St. Annes-on-sea; 2nd prize, Mr. Rudini, Blackburn; 3rd prize, N. S. Kay, Manchester. Section 2 (artificial light): 1st prize, N. S. Kay, Manchester; 2nd prize, C. E. Willis, Bolton; 3rd prize, N. S. Kay, Manchester. Section 3 (commercial photography): 1st prize, W. T. Carter, Rochdale; 2nd and 3rd prizes, C. E. Willis, Bolton. Section 4 (colour work): 1st prize, N. S. Kay, Manchester; 2nd prize, C. E. Willis, Bolton; 3rd prize, Mr. Care, Eccles. The question of the nature of awards to be given to the winners was then discussed, and it was decided to ask the exhibition committee to deal with this matter and bring forward their recommendations at the next committee meeting.

A very important matter was then discussed regarding assistants leaving without notice, and at the invitation of the president, Mr. J. S. Brown attended the meeting in order to explain to the committee how he had been treated by a member of his staff quite recently. He had left this individual in charge of his business during his absence at the conference in Blackpool, and on returning found that his studio had been closed for two days, and the assistant in question informed Mr. Brown upon his return that she had no desire to return to her work. In consequence of this action Mr. Brown was very much inconvenienced. Mr. Howell quoted a case of a youth at the age of 17 years whom he had engaged quite recently at 45s. per week. After receiving his money on the Saturday, he informed one of his fellow workers that it was not his intention to return. He was then asked if he did not think Mr.

Howell was entitled to a week's notice. His reply was that that was the seventh job he had had in seven weeks, and had not given notice to any one of them. Several cases were quoted by members of assistants having been engaged from different parts of the country and their expenses paid on the understanding that they were perfectly qualified. It was discovered, however, when work was placed in their hands, that they were utterly incompetent, and on several occasions many pounds' worth of work had been spoiled. The question having been discussed at some great length, and many members having given their experiences, the president stated that he considered the time had arrived for some drastic measure to be taken by the members of the society. He would suggest that the secretary be instructed to draft an agreement which could be submitted to the next meeting of the committee, and, if approved, this should be used by every member of the society. Mr. Winter proposed the adoption of the president's suggestion, and would embody in his proposal that the secretary be instructed to retain the services of a solicitor to take up Mr. Brown's case, and, if necessary, to take it into the Court and make a test case of it. Also, that the secretary approach several solicitors with a view to making arrangements for retaining the services of a professional man to watch the legal interests of the members of the society. This proposal was seconded by Mr. Howell and carried unanimously.

The question of sick pay was also fully discussed, and several members gave their experiences with regard to this matter, it being decided after a lengthy discussion that the secretary embody a clause in his draft agreement to govern this question.

Assistants' specimens. This question, the president reminded the members, had been brought forward by Mr. N. S. Kay, the past president, in his address at Blackpool, and the members would remember that he stated a very clear case of how an assistant had traded upon the work of Mr. Kay and had tried to pass it off as his own. Mr. Kenworthy stated that he had given this matter a great deal of thought since the annual meeting, and he would suggest that the assistants be allowed a set of specimens before leaving the employment of any member, these specimens to be secured from time to time by the assistants and submitted to the employer, and if the employer was satisfied that it was the work of the assistant, he, the employer, should sign the specimens accordingly and forward them on to the secretary of the society to be endorsed by the seal of the society. On an assistant leaving the employer, a covering letter should be given to each assistant intimating that the specimens submitted were the work of that assistant. This letter should also bear the crest of the society. It was generally felt that the suggestion of the chairman was a very practical one and would help them considerably to do away with the practice that had been outlined at the annual general meeting by Mr. Kay, and that the adoption of the chairman's suggestion would be for the benefit of every practical assistant as well as for the employer. Mr. Greenwell then proposed that the chairman's suggestion should be adopted, this proposal being seconded by Mr. Beck and carried unanimously.

A letter from the secretary of the Birmingham Photographic Society was read by the secretary, in which information was asked regarding the attitude that had been taken up by the members of the Society of Master Photographers with regard to the proposed scheme of the Ministry of Labour for training disabled soldiers, and after a very lengthy discussion the secretary was instructed to write to the Birmingham Photographic Society informing them that at a general meeting of the Society of Master Photographers held some time ago it was unanimously decided that the scheme of the Ministry of Labour with regard to the training of disabled soldiers could not be encouraged in consequence of the very short training suggested, it being considered that at least five years should be spent by an apprentice in order to learn his profession properly.

The question of members' certificates was brought up by Mr. F. Read, and it was decided that these certificates should be put in hand, and the exhibition committee should be asked to pass a draft proof of same.

The committee decided to hold their regular monthly meetings on the third Tuesday of each month at the office at 39, Blackfriars Street, Manchester, and general meetings of the society to be held

from time to time in different parts of the Lancashire and district area.

A vote of thanks having been proposed to the president, this concluded the business of the meeting.

AFFILIATION OF PHOTOGRAPHIC SOCIETIES' SUMMER OUTING.—The removal of all restrictions on photography and the return of so many men to civilian life and pursuits resulted in a large attendance, and the outing on June 21 in the Croydon district was characterised by much of the enthusiasm and cheerfulness of pre-war gatherings. The weather was very favourable for outdoor work, which was only suspended for a short time while a thunder-storm passed over about midday. This caught one eminent pictorialist on the top of Croydon, searching for "the spirit of June," and considerably damped his enthusiasm by soaking him to the skin. During the morning a number of plates were exposed in Whitgift Hospital, the old Archbishop's Palace, and the parish church. The afternoon trains brought down heavy reinforcements from town, which spread themselves over the route along the Wandle from Croydon to Wallington, where they were eventually all gathered together for tea, with the assistance of Croydon Camera Club guides. On the conclusion of tea the chairman of the affiliation, Mr. T. H. B. Scott, addressed the meeting, and reminded those present that the insignificant river they had wandered by bore a name which was an emblem of hope to the nation at the darkest period of the submarine menace, as the first U-boat successfully engaged by a merchant vessel was the one sunk by the little collier "Wandle," which received a most enthusiastic ovation when she came up the Thames to her wharf at Wandsworth. He referred to the desirability of a closer bond of sympathy and co-operation between the affiliation and the northern Federations, and in connection with this expressed the appreciation of the meeting at the presence of Mr. F. G. Mott, of the Yorkshire Photographic Union. He concluded by moving a vote of thanks to the Croydon Camera Club for its successful arrangement of the outing, which was responded to by the president of the club, Mr. John Keane. Mr. F. G. Mott cordially reciprocated the chairman's remarks as to the prospect of a better understanding being encouraged between the northern and the southern photographic bodies.

Commercial & Legal Intelligence.

NEW COMPANIES.

BLACK CAT STUDIOS, LTD.—This private company was registered on June 11, with a capital of £1,000 in £1 shares. Objects: Photographers, etc. The subscribers (each with one share) are:—J. E. Pickup, 55, Rochdale Road, Blackley, Manchester, and T. L. Cooper, 54, School Road, Sale, Cheshire, antique dealer and photographer. The first directors are J. E. Pickup and T. L. Cooper. Registered office, 15, Market Street, Manchester.

F. W. MILLER AND Co., LTD.—This private company was registered on June 13, with a capital of £5,000 in £1 shares. Objects: Enamellers and makers of articles of personal adornment, ceramic photographers, etc. The subscribers (each with one share) are:—F. W. Miller, Aylesbury Road, Hockley Heath, near Birmingham, manufacturer; A. Allen, 66, Nansen Road, Sparkhill, Birmingham. The first directors are F. W. Millar, J. W. Simcox, and A. Allen. Registered office, 68, Nansen Road, Sparkhill, Birmingham.

S. A. CHANDLER AND Co., LTD.—This private company was registered on June 17, with a capital of £5,000 in £1 shares. Objects: To acquire the business of photographers, picture framers, and stationers carried on at Exeter and Southampton by S. A. Chandler. The subscribers (each with one share) are:—S. A. Chandler, photographer, fine art dealer, and stationer, Beach House, Topsham; Mrs. S. Chandler, Beach House, Topsham. Directors: S. A. Chandler and Mrs. S. Chandler. Solicitors: G. H. Kite and Sons, Taunton.

UNITED KINGDOM OPTICAL Co., LTD.—This private company was registered on June 18 with a capital of £100,000 in £1 shares (50,000 7 per cent. cumulative preference and participating). Objects: To take over (a) the business carried on by the Crescent Lens Co., Ltd.,

incorporated in 1918, (b) all or part of the plant, tools, patents, etc., of George Culver, Ltd., incorporated in 1897, and (c) an exclusive licence to work the secret process for moulding spectacle lenses and the like now worked by or under the control of the Precision Lens Moulding Co., Ltd., incorporated in 1919; to engage the services of A. H. Emerson, of 2, Chase Court Gardens, Enfield, as an inventor and secret process worker, expert adviser, and skilled operator; to acquire the freehold factory at Mill Hill and fixtures therein, formerly the property of Carl Zeiss, of Jena, Germany, but recently acquired by Ross, Ltd.; and to carry on the business of manufacturers of and dealers in spectacles, eyeglasses, goggles, lenses, photographic, marine, astronomical, and scientific instruments, etc. Special clauses are inserted in the articles of association to ensure against foreign control and to comply with the Board of Trade requirements against trading with the enemy. No enemy may be a director, and not less than three-fourths of the board, including the chairman, must be British subjects resident in the United Kingdom. The subscribers (each with one ordinary share) are:—G. W. Bayliss, 124, Queen's Road, Finsbury Park, N., manufacturing optician; E. Culver, 42, Coolhurst Road, Crouch End, N., manufacturing optician. The first directors are:—F. W. W. Baker, Queen's Road, High Barnet (chairman), G. W. Bayliss, E. Culver, S. Culver, 2, Deane Mansions, Dennington Park Road, N.W., and A. H. Emerson, 2, Chase Court Gardens, Enfield, all manufacturing opticians. Qualification, £250. Remuneration of chairman, £200; of others, £100 each per annum. Solicitors, Snow, Fox and Higginson, 7, Great St. Thomas Apostle, E.C.

News and Notes.

SIGNOR GIUSEPPE FORNASARI, general representative for Italy of Messrs. Rajar, Limited, Moberley, England, on the proposal of the Under Secretary for War and Ammunition, has been appointed Knight of the Crown of Italy.

THE PROBLEM OF ENLARGEMENTS.—An interesting brochure under this title has been issued by the London News Agency Photos., Ltd., which puts the case for enlargement from amateurs' negatives in a forcible way. It is illustrated with blocks which show how three well-composed and quite distinct pictures can be made from one rather overcrowded negative.

PHOTOGRAPHING A MIRAGE.—We have received from Mr. G. F. Quilter, of Ingatstone, an interesting photograph of a mirage effect seen on the 15th inst. Although there had been no rain for days, there was from a certain point the appearance of pools of water in the road, in which the reflection of certain objects could be clearly seen. Mr. Quilter has taken careful notes of distances, angles, the position of the sun, etc., which he is willing to communicate to any scientific investigator of the phenomenon.

NAVAL PHOTOGRAPHS.—The steps being taken to obtain a photographic record and collection of all ships which flew the White Ensign during the war now include an appeal to all photographers in the Navy to lend their aid. In an Admiralty Order just issued, to which the Admiralty desire that the utmost publicity may be given, it is stated that:—

1. It is desired to obtain as complete a collection as possible of photographs of all ships which flew the White Ensign from 1914—1918 for the Imperial War Museum and Admiralty Records, and for this purpose it is especially requested that all officers and men who have negatives of ships, actions, damages or incidents of interest in connections with the war will lend them to the Secretary of the War Museum for inclusion in the collection.

2. All photographs sent in will be acknowledged, and copies will be made from those which are considered suitable and the negatives returned without delay.

Those not used will be acknowledged and returned at once.

The above applies to:—

(a) Any official photographs which have not yet been sent to the Admiralty. Such photographs would be taken with service materials supplied free for the purpose, and the negatives would remain the property of the Admiralty.

(b) To photographs taken by officers with materials purchased at their own expense, whether from service sources or elsewhere.

3. As it is proposed to open for sale prints of all photographs in the

War Museum collection, it is requested that in cases falling under (b) the donor will state his agreement to this condition in a covering letter. The proceeds of such sales will be applied towards the cost of the Imperial War Museum. Apart from these sales, the copyright remains in the hands of the owner of the negative, and officers and men are free to dispose of it as they please, subject to the condition that the photo should first be submitted to the Commanding Officer who will decide whether it contains anything of a confidential nature which should not be disclosed.

4. Permission to dispose of photographs under the above conditions extends to all photographs whether taken before or after the armistice.

5. An enlargement or prints, as desired, will be included with each accepted negative on return in acknowledgment of the gift.

6. Glass negatives should be well packed in boxes—not merely between cardboard and wrapping—and addressed to:—The Director, Imperial War Museum, Photographic Depot (Naval Section), 12, Coventry Street, W.1.

7. The Admiralty desires that the utmost publicity may be given to this matter, and the order should be copied and circulated throughout the ship or establishment.

Correspondence.

* * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

NEW SIZES OF PLATES

To the Editors.

Gentlemen,—Seeing that the British plate manufacturers (very sensibly, I think) wish to gradually do away with some useless sizes of plates, I write to ask why not adopt the 10 x 14 in., 7 x 10 in., 5 x 7 in., 3½ x 5 in., and 2½ x 3½ in.? These sizes would cover all classes of work, and if the operator purchased the larger size and wished a smaller, all he would have to do would be to cut a plate exactly in half. If a smaller size yet, then cut exactly in half again, and so on down to the smallest (2½ x 3½) size. The two largest sizes give plenty of room for artistic work, and are sensible shapes.

The 5 x 7 is a fine stereoscopic and portrait size, and is convenient for all-round work. The 3½ x 5 makes fine postal cards, lantern slides, etc., while the 2½ x 3½ fills all the requirements for a pocket camera. Another advantage is that all these sizes correspond practically with the metric system, so that they would always fit the holders anywhere in the world. I explained this somewhat in the "American Annual of Photography" for 1919, but I think if you publish this in your excellent journal your readers will not be slow to see the advantages. Wishing you success,—I am, yours truly,

H. W. HALES

95, Spring Avenue, Ridgewood, New Jersey, U.S.A.

LENSES.

To the Editors.

Gentlemen,—It is to be feared that the condemnation by "Practicus" of the use of the Petzval portrait lens (the usual portrait lens) for outdoor work may, if allowed to pass unchallenged, deter inexperienced workers from the use of an instrument which they possess, and which might be of great service to them. In the days of collodion I invariably used it for equestrian portraiture, and at the Haverstock Hill studio I had a background fitted up in the garden, and photographed many children, and sometimes adults, there for the benefit of the rapid outdoor exposure. Not in a single instance did I experience either flare or ghost. I also knew a photographer in the country who habitually used his portrait lens for outdoor portraits (he had no studio), groups, churches, and houses.

If "Practicus" has been troubled in the way he describes, it is probable that his experience has been not with the true Petzval lens but with that variation from it in which the elements of the

back lens are reversed in position. As has been pointed out by Mr. Chapman Jones, lenses of this construction are particularly liable to furnish "ghost" images, as, indeed, might be looked for from the fact of there being three glass surfaces concave to and behind the diaphragm, instead of one as in the original Petzval.

"Practicus" also speaks of the portrait lens having a more deeply curved field than the rapid rectilinear—a fancy name for the lens invented by Steinheil and called by him the Aplanat. Here again, I think the writer must have had in mind the variation of the Petzval already mentioned. Some years ago I ordered for a brother photographer, from a maker of the highest standing, a lens similar to one that I had in use. On trying it in the camera before sending it off, I found that the field was more curved than in my own lens, and on examining the instrument I found that the back lens was of the reversed curvature kind. I sent it back to the maker and was supplied with a satisfactory lens of the same character as my own—Yours faithfully,

W. E. DEBENHAM

ASSISTANTS' WAGES.

To the Editors.

Gentlemen,—"An Employer's" letter of the 13th inst. in reply to my letter of May 30 appears to challenge some of my statements, and I consider it is up to me to substantiate the remarks in question. In the first instance I was not speaking for myself alone, but for assistants in general, against the unfair treatment and inadequate wages that have been and are still offered. If "An Employer" cares to look through the "Situations Vacant" adverts. for May he will come across the ones that prompted me to write my letter on this subject. Unfortunately I have not the copy with me of the "B.J." in which they appeared, but the case to which I allude in particular was for an "Operator-Retoucher," or "Operator Manager" for a "London Suburb" at £2 per week. Besides this, there were adverts. for bromide printers, also London, at the same salary; one was worded: "Good Bromide Printer," and another asked for a "Finisher-Retoucher able to operate," at the same highly remunerative salary. As regards keeping situations open for their pre-war employees, one employer I know personally promised to keep the berths open for his men when they enlisted. Those who have returned have been re-instated at a salary equivalent to their previous rate, and, moreover, he has retained his temporary staff of girls till they have been able to secure suitable situations elsewhere. These are the kind of employer one does their utmost for, putting their heart into the work. On the other hand, a certain employer agreed to accept his men back after their service with the colours. Those who did return were informed that he got on very well with female labour, at about half the price it would cost him were he to re-engage them, therefore he had no further need of their services.

Even before the war an all-round man never was paid the wage he deserved although able to assist in all branches of the trade, but the specialist in operating, retouching, finishing, etc., could command a far better wage. Do employers ever stop to consider how useful the all-round man is? especially in a small studio, since he is able to take the work right through, start to finish, working for a low salary, simply because he is only a "general assistant." "Another Assistant" who writes in the "B.J.," June 20, appears to be an ex-service man, and judging from his letter has come in contact with the "War Products"; possibly had an experience of them whilst in the service; if so, he has my sympathy. I quite agree with "Another Employer" in a number of his remarks, but to quote them would trespass too much on the space provided for "Correspondence."

In concluding, I might say I fully agree with both "Another Assistant" and "Another Employer" in requesting "An Employer" to publish the hints he alludes to through the valuable pages of the "B.J." for the benefit of innumerable assistants who take a pride in the work they execute—Yours faithfully

AN ASSISTANT.

FORTHCOMING EXHIBITIONS.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

G. S. S.—The "Salex" lens is one issued by the City Sale and Exchange, 81, Aldersgate Street, E.C.1. At the present time, second-hand lenses, except of the best makes, are worth about three-quarters of the present list price.

E. Y. E. N.—There have been one or two French books on the subject, and one issue of the "Photo-Miniature" series, but all are now out of print. In the "B. J." of January 17, 1917, an article on pinhole photography appeared which might be of some service to you.

W. W.—Bromide postcards can be burnished by hot rolling, although the gloss is not as good as that by stripping from glass. It is more like the satin surface of some bromide prints. We should think you ought not to pay more than 30s. to £2 for a second-hand burnisher.

B. W.—There is no practical advantage in forming the hydrochloric acid for the platinotype clearing bath by mixing chloride of sodium and sulphuric acid, nor in our opinion in adding chloride of sodium to the hydrochloric acid bath. There is no better clearing solution than dilute hydrochloric acid, and it is quite effective in removing iron salts.

G. H.—The arrangement you describe is that adopted in the Bergheim lens and is a very good one; both lenses are of the same focal length, positive and negative, and when in contact will not produce an image. This is done by separating them. A simple plano-convex lens of crown glass will also give good results. Everything depends on the amount of softness you require.

R. H.—As you will not be trading under your own true Christian name and surname it will be necessary to register. Forms for the purpose can be obtained from the Registrar of Business Names, 39, Russell Square, London, W.C. No licence is necessary if the change is merely one of transfer of ownership. If you add any other accessory for retail sale, then a licence will be necessary.

A. E. THOMAS.—Your suggestion of a cylindrical lens to cure the marginal distortion is not practical as the definition all over the plate would be affected. The only remedy is to use a panoramic camera in which the lens points directly at each part of the field in turn. If you used a lens with a curved field and curved the film so that the ends came into focus, it would reduce the defect but might not quite cure it.

W. A. J.—If, as you say, the lens of the V.P. Klimax is set to 24 feet, naturally an object at that distance will be the sharpest, and at other distances the objects will only be approximately sharp. So far as we know there is no rule which can be applied in your case. Your best course will be to examine the image of objects placed at different distances with the lens set at 24 feet. Of course, an exceedingly finely grained screen must be used.

N. N.—We do not undertake registration of trade marks which, we take it, is what you wish to do in reference to the portraits. For this you should apply for a circular of instructions to the Controller of Patents and Trade Marks, 25, Southampton Buildings, Chancery Lane, London, W.C.2. This will have nothin

to do with the copyright in the portraits themselves which, as you doubtless may know, is created automatically by the taking of the portraits and without any registration as formerly.

R. B. T.—1. The lamps should be about 8 ft. from the floor for standing figures, and 6 ft. 6 ins. for sitting. If you want rapid exposures, at least another 1,000 c.p. is necessary. With such large reflectors a white diffuser, say 12 ins. square, should be enough. 2. You do not give size of plates you intend to use. Seven inches is far too short a focus for half-plates; at least 9 ins. is necessary to get good perspective. F/6.8 is a rather small aperture for artificial light. White walls will help to shorten exposure, but beware of flatness. The sloping roof will be of no advantage. It will not reflect light where it will be of any use.

A. M. G.—We are not surprised that you are not satisfied with the results which you obtain with the lens you mention. This we find has a focal length of 6 ins., quite suitable for general work, but far too short for 5 by 4 portraits. You mention 1½ ins. as the maximum size of head you require. Now, considering that in life a head averages 9 ins. in height, you want a reduction to 1-6th scale, and the distance between lens and sitter for this has to be seven times the focal length—in your case 3 ft. 6 ins. This is much too short, the minimum allowable distance being 5 ft., which would call for a 9 in. lens; 10 ins. would be better. You need not change your camera, but you should certainly change the lens, or else get an additional one of the necessary focal length.

C. H. E.—1. You might be able to procure a very pale yellow "pot metal" glass from Messrs. J. Hetley and Co., Soho Square, London, W.1, but we think your best course would be to fix only an ordinary plate without exposing and dye the gelatine a very light yellow tint. This you can do with Judson's or other similar dye. If you have a pronounced yellow it will, of course, prevent all action on the bromide paper. We do not think you will gain anything by using green or blue glass for dense negatives, but in the same way you could dye plates in these colours for trial. 2. The K2 filters are made by the Wratten division of the Kodak Company, Ltd., Kingsway, W.C.2, who will send you full particulars and prices. The filters may be used in front of the lens, but as a rule are better placed behind it.

Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.
(No reduction for a series.)				

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add ... 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed Adv'ts should reach the Publishers on Monday morning.
The insertion of an Advertisement in any definite issue cannot be guaranteed.

SUMMARY.

This week's instalment of "Stereoscopic Photography" deals mainly with giant vision work from widely separate points, as in astronomical and mountain work. (P. 378.)

Although the thermometer now stands in the fifties, the note on fog due to high temperatures will enable our readers to cope with the trouble in the near future. (P. 377.)

The second part of Mr. J. I. Crabtree's paper on the making-up of solutions is devoted to the manipulative details, such as filtering, dissolving, and concentration. (P. 379.)

The production of imitation wood grain on metal for decorative purposes, the inadvisability of trying to patch up an unsatisfactory job, and the working-up of originals for reproduction are the subjects of "Photo-Mechanical Notes." (P. 385.)

The lay-out and fittings of a typical dark room of small dimensions is the subject dealt with by "Practicus" on page 382.

Under "Patent News" will be found abridged specifications relating to colour cinematography and the preservative packing of roll and flat films. (P. 386.)

Some useful hints in regard to weighing, filtering, and plating, given at the Croydon Camera Club last week, are reported on page 386.

The effect of temperament upon a man's chances of advancement is discussed in "Assistants' Notes" on page 384.

A letter from a correspondent on page 387 gives an idea of the difficulties with which photo-button workers and ferrotype workers generally have to contend with just now.

Flattening cards, precipitating residues, masks for white-margin printing, tank development, and focal-plane cameras are among the subjects dealt with in "Answers to Correspondents" (P. 388.)

"COLOUR-PHOTOGRAPHY" SUPPLEMENT.

It is well known that the colour rendering in Autochromes is greatly affected by the nature of the illumination used, when this is other than daylight. Some practical information on surmounting this difficulty is given on page 25.

The current instalment of "Decennia Practica" is devoted to simplified processes of colour photography by prismatic dispersion, and includes the methods of Raymond, Poirée, and J. and E. Rheinberg. (P. 27.)

It will be interesting to many to learn that a bleach-out photograph of the spectrum made eleven years ago is still in its pristine condition. (P. 28.)

In colour cinematograph projection, when alternate red and green positives are used, there is a sort of shock to the eye caused by their rapid succession. To overcome this, it is proposed to alter the sequence. (P. 26.)

EX CATHEDRA.

A Dry Mounting Hint. There are many people who are waiting for the price of apparatus to fall to a little nearer the pre-war level who are desirous of dry-mounting a few prints occasionally, but who cannot afford the cost of a press. In these circumstances it is usual to do one's best with an ordinary laundry iron. Often the attempt is unsuccessful, and this may be due to one or more of several causes, of which one is unsuitable tissue. During the war some of this tissue was difficult enough to use even with a heavy press and suitable mounts, as it required a high temperature and great pressure. This quality would be clearly unsuited to the flat-iron method, which requires an easily melted tissue. Another mistake is to use too light an iron: if it can be obtained, a heavy laundry iron or a tailor's goose should be used instead of the small thing found in an ordinary house. When ironing the print on to the mount the iron should be pressed firmly first on one part of the print and then on another, a smoothing action as in ironing a collar is useless, as directly the iron is moved away the print springs up. A piece of very thin hard paper should be placed on the face of the print, for if the iron comes in contact with it, shiny patches are likely to appear. Strips of tissue are excellent for "tipping" prints on to mounts, as they do not cause any cockling or unevenness of the surface at the corners, which frequently occurs when paste is used.

* * *

Temperature and Chemical Fog. It should not be forgotten that, besides the fog which is caused by diffused light in any form falling upon plates and papers, chemical fog which is caused by the action of the developer upon unexposed silver bromide has sometimes to be reckoned with. Most of us are familiar with that form of it which arises from adding an undue quantity of alkali to a pyro developer in the vain hope of "forcing" out detail upon an under-exposed plate, but we often forget the fact that a high temperature has exactly the same effect as a large dose of alkali, which is to hasten development and so to arrive quickly at the point at which the unexposed haloid salts begin to be reduced. There are several ways of meeting this hot-weather trouble. A simple one is to reduce the quantity of alkali in the developer. One well-known formula calls for eight ounces of soda carbonate to each ounce of pyro. In very warm weather this can be reduced to one-half with advantage, and a further control may be obtained by the addition of a little bromide solution. Even with the amidol developer there is in the same circumstances a tendency to produce chemical fog, but the deposit is of a yellowish colour, readily recognised by anyone who has tried to develop out a much under-exposed print, with the difference that in hot weather the stain rapidly appears. Here, again, bromide is more or

less a cure, but the real remedy, or perhaps more correctly, preventive, is to reduce the temperature of developer by the addition of a little ice, or, better still, by putting the developer in an ice-box or refrigerator. A simple contrivance to serve this purpose is a wooden pail with a lump of ice in the bottom and a stand for the bottles above, a pad of several thicknesses of wet blanket serving as a lid. When raising or lowering the temperature of solutions, it is very desirable to use a thermometer, so that a moderate temperature can be obtained. With developers containing hydroquinone temperature is an important factor, and a drop below 50° Fahr. seriously affects their action. A simple but practical way of partly meeting hot weather troubles is to develop either very early in the morning or late at night. This is healthy for the operator as well as for his work, as less time is spent in the dark-room during the heat of the day.

STEREOSCOPIC PHOTOGRAPHY.

IV.—“GIANT VISION.”

We have spoken, in a previous article of this series, of lenses at a separation distance equivalent to that of the eyes, and for ordinary stereoscopic effects this is obviously the proper arrangement. For certain special effects, however, a very much wider separation of the lenses is admissible and even requisite.

In a paper devoted to scientific queries and replies there appeared a few years ago a question as to stereograms of

standpoints. In the case of stereograms of the stars, such as the beautiful series prepared and published by the late Mr. T. E. Heath, of Tenby, the imaginary view-points had to be separated by 100 light-years instead of 3 inches. A light-year means the enormous distance traversed by light in a year when journeying at the rate of some 180,000 miles a second. These star stereograms give us, in fact, the view that a celestial giant with eyes 100 light-years apart would have of the principal constellations in our universe. Such stereograms are, of course, hand-drawn, and the positions are arrived at mathematically, but the giant-vision principle on which they are based is identical with that of the giant-vision stereograms produced with the camera.

It is obvious that a difference in view-points of three inches, while it may make an appreciable variation in the images of near objects, can have no perceptible effect on the images of distant things. The trees and houses near the horizon in an ordinary stereogram must be to all intents and purposes identical in configuration in the two halves of the stereogram, yet so marvellously sensitive is the eye that differences quite immeasurable do as a matter of fact suffice to give stereoscopic effect, and beyond that point the effect is presumably produced by the context of the picture—i.e., the relief of contiguous parts and the strong relief of the foreground.

But if we desire to produce really marked stereoscopic effect as regards distant objects we must have recourse to the plan of taking two views similar in size from two

Bruges from the Belfry—an example of giant-vision stereoscopy. By C. E. B.

the moon and how they are taken. In the following issue some one whose little learning was a dangerous thing seriously suggested the use of a twin-lens camera, and gave an instructive account of the principles of stereoscopic photography! It was almost as bad as the idea of parallax displayed by the cockney when Halley's comet was visible. "Come over this side of the street, Bill; you catch it edgeways." For a stereogram of the moon, 240,000 miles away, it need hardly be said a difference of 3 inches in the two view-points would not suffice. It is only by taking advantage of the moon's librations that we are able to get views which differ sufficiently to give stereoscopic effect. The Chicago University series of astronomical photographs includes, besides lunar stereograms, stereograms of comets taken by successive photographs of a comet at appropriate intervals of time, giving thus the equivalent of views of the comet from two widely separated

widely separated points. The effect when two such images are placed at our 2½-inch distance and combined with the aid of the stereoscope is that of a small model of the scene, in fact it is just such a view as we might suppose a Brobdingnagian giant would have of our Lilliputian landscape. Hence they may be appropriately called giant-vision stereograms.

What is required for these is some elevated plateau, enabling us to take widely separated views of a distant object—say a village, a town, or a mountain without any intervening foreground. The effect is quite a revelation. It is almost as if a telescope had been applied. There is no enlargement—rather the reverse—and yet every undulation of the ground is so vividly shown that our vision is decidedly enhanced as if by telescopic aid. The same thing may be said of the lunar stereograms which show the markings on the moon so expressively that they seem

to add extra telescopic power to that of the telescope used to produce them.

A single camera is, of course, all that is required for these giant-vision stereograms, which must be taken successively. The subject must be one in which no change in the scene is likely to occur between the two exposures. Crowds or moving objects must not enter into the view. A day must be selected, moreover, in which the lighting is steady and uniform. The view from Bruges belfry, reproduced herewith, was from standpoints not more than 12 feet apart. In mountain countries a plateau of table land often affords an excellent opportunity for securing a good giant-vision stereogram of a fairly distant peak or a glacier. At Murren in Switzerland there is an ideal terrace of this kind, facing the famous range of peaks so well known to the tourist.

Clouds may be taken, or indeed any moving objects, if two cameras are used and simultaneous exposure by two photographers is arranged for by signal. For clouds, several hundred yards' interval should be allowed. There are days on which very fair cloud stereograms can be produced without changing the camera's position at all, but simply allowing the cloud to change its position instead. One photograph is taken, and then you literally "wait till the cloud rolls by" and take another. Such effects can be obtained only when cumulus clouds well defined and of fairly persistent shape are drifting across the sky. A colour screen should, of course, be placed before the lens as usual in cloud photography.

The giant-vision stereogram was of great service during the war. So sensitive is the eye to any lack of due correspondence anywhere in the two halves of a stereogram that such a defect shows itself at once, the unmatched speck starting out far away from the plane of the picture. For this reason when two photographs had been taken on successive days of the enemy's position from an aeroplane the minutest change could be instantly detected by combining the pictures stereoscopically. Camouflage tricks were also exposed by the giant-vision stereogram, which made short work of the pretended haystack when its lack of cubic form was revealed in the stereoscope.

In astronomy the tedious comparison of star charts is got over very helpfully by stereoscopic combinations of charts taken at intervals of many years. Any alterations of position of celestial bodies, any new stars, or any stellar disappearances are promptly revealed. No doubt the stereoscope might be used effectually (if such a use has not already been applied) to detect any possible alterations of the lunar surface by combining in the stereoscope the oldest existing lunar photographs with the latest, taken under similar conditions of solar illumination on the moon's surface. The solar corona at the time of an eclipse is a very important subject for stereoscopic treatment. A few years ago a special opportunity occurred, and the view-points of Egypt and Alaska were to have been utilised for the two photographs. Unfortunately the Alaskan sky was clouded, so that the project was not accomplished.

C. E. B.

HOW TO PREPARE PHOTOGRAPHIC SOLUTIONS.

[In the following paper, a previous instalment of which has already appeared, Mr. J. I. Crabtree of the Eastman Research Laboratory, deals in a most explicit and comprehensive way with the practical methods of making up photographic solutions in bulk and with the chemical proportions which require to be taken in accordance with the properties of the substances which are being handled. Although contributed for the information of cinematograph photographers to the "Motion Picture News" there is scarcely a single paragraph of it which does not apply to the customary operations of any photographer working upon a reasonably large scale; and there is, we think, no photographer so fully expert in the compounding of such solutions as developers, fixing baths, etc., who will not get some practical hints from it.—Eds. "B.J."]

(Continued from page 368.)

Filtering

THE purpose of filtering is to remove suspended matter such as dirt, caused by the presence of dust in the chemicals used, and also any residue or undissolved particles which might settle on the plates, film or paper during development. There are several methods of removing such particles as follows:

1. Allow the solution to stand and draw off or decant the clear supernatant liquid. This method is particularly useful when the suspended matter is so fine that it will pass through a coarse filter.

Since coarse particles settle quickly the rate of settling of a semi-colloidal sludge can usually be hastened by mixing the solution in hot water, because the heat tends to coagulate the suspension and causes the particles to cluster together. Thus if crystals of sodium sulphide which are brown due to the presence of iron are dissolved in hot water the colloidal iron sulphide coagulates and settles out rapidly leaving a perfectly colourless solution.

2. Filter the solution through fabric or filter paper. Filtering through paper is usually a slow process, and the continual dropping of the solution exposes it to the air, thus causing oxidation. It is usually sufficient to filter through very fine cloth or muslin which has been washed thoroughly, otherwise the sizing matter in the fabric will be washed into the solution and settle out as a sludge.

3. As a modification of method 2, when mixing a quantity

of solution in a tank, stretch a filter bag made of cloth over the tank, place the chemicals in the bag (about 6 inches deep) and allow hot water to flow into it. In this way the chemicals are dissolved, and the solution filtered at the same time. A separate

Fig. 1.

big should be used for each solution so as to eliminate all risk of contamination.

The method of supporting the bag is shown in Fig. 1, the bag being stretched over a wooden frame, and held in place by means of four iron bars passing through loops along the edges of the bag. For mixing hypo, such a bag is indispensable.

In the case of deep tanks such as are used for developing roll film, and for motion picture work, the wooden frame can be dispensed with by adopting the arrangement shown in Fig. 2. The cloth bag about 6 inches deep is supported by means of iron bars passing through seams along opposite edges of the bag, and in turn the bars are held in place either by means

Fig. 2.

of two pieces of wood passing over the ends of the bars as shown or by metal stirrups fitted to the sides of the tank.

It is important that the bag used should be shallow (6-9 inches deep), otherwise it will dip into the solution, and the chemicals will dissolve very slowly.

Fig. 3.

4. A combination of methods 1 and 3 is the best and most desirable as follows:

(a) For quantities of solution up to 5 gallons, filter through cloth into a bottle or crock fitted with a side tube and pinch cock. In this way the fine particles settle out, but the drainage tube is sufficiently high so as not to disturb the sediment. (See Fig. 3).

(b) For motion picture work the best arrangement for mixing is to place the chemical room immediately above the developing room, and to mix the solutions in large wooden vats or enamelled tanks connected with lead piping to the developing and fixing tanks in the dark room underneath. The solutions can then be mixed in advance, allowed to settle and tested, so that only perfect solutions pass into the tanks located in the dark room.

Removing Scum.

When mixing a chemical solution, if method 4 above is not adopted, and especially if the solutions are not filtered, a scum usually rises to the surface consisting of fibres, dust, etc., which should be skimmed off with a towel.

When a fixing bath has been used for some time, and is allowed to stand undisturbed for a few days, any sulphuretted hydrogen gas which may be present in the atmosphere forms a metallic-looking scum of silver sulphide at the surface of the liquid, and on immersing the film this scum attaches itself to the gelatine, and prevents the action of the developer. Any such scum should be carefully removed before use with a sheet of blotting paper.

Measuring Temperatures.

Temperatures of solutions are measured either by the centigrade or Fahrenheit thermometer. On the centigrade scale water freezes at zero degrees and boils at 100°, and on the Fahrenheit scale the corresponding readings are 32° and 212°, so that 100° C. are equivalent to 212° - 32° = 180° F. or 1° C. is equivalent to 9/5° F.

To convert degrees Centigrade to Fahrenheit, multiply by 9/5 and add 32. To convert degrees Fahrenheit to Centigrade subtract 32 and divide by 9/5.

In photography the Fahrenheit thermometer is almost universally employed. There would be no appreciable advantage in adopting the Centigrade scale, while the precision of the Fahrenheit scale is greater since an error of 1° in reading the Centigrade scale means an error of practically 2° on the Fahrenheit scale.

How to Mix Developing Solutions

A developer usually contains four solid ingredients as follows:

- A. The developing agent (Elon, hydroquinone, pyro, para-aminophenol, etc.)
- B. The alkali (carbonates and hydroxides of lithium, sodium, potassium and ammonium).
- C. The preservative (sulphites, bisulphites, and metabisulphites of sodium and potassium).
- D. The restrainer (bromides and iodides of sodium, potassium and ammonium).

If a developing agent like hydroquinone is dissolved in water, the solution will either not develop at all or only very slowly, and on standing it will gradually turn brown due to what is known as oxidation or chemical combination of the hydroquinone with the oxygen present in the air in contact with the surface of the liquid. This oxidation product is of the nature of a dye and will stain fabrics or gelatine just like a dye solution.

On adding a solution of an alkali such as sodium carbonate, the hydroquinone at once becomes a developer, but at the same time the rate of oxidation is increased to such an extent that the solution very rapidly turns dark brown, and if a plate is developed in this solution it becomes stained and fogged. The subject of "Chemical Fog" has been fully treated by the author in a separate article (Amer. Ann. Phot., 1919) to which the reader is referred.

If we add a little sodium bisulphite to the brown-coloured solution mentioned above, the brown colour or stain is bleached out and a colourless solution is obtained. Therefore, if the preservative is first added to the developer, on adding the accelerator the solution remains perfectly clear, because the sulphite

preserves or protects the developing agent from oxidation by the air.

As a rule the preservative should be dissolved first.

An apparent exception to this rule should be made when dissolving Elon in concentrated solution, since this developing substance is insoluble in a strong solution of sodium sulphite, while if a sulphite solution is added to a strong solution of the developing agent a white precipitate is formed.* When once the Elon is dissolved, however, it takes a fairly high concentration of sulphite to bring it out of solution again, though only a low concentration is required to prevent the Elon from dissolving.

On this account some direction-sheets recommend that the Elon should be dissolved first, though if water containing dissolved air is used the Elon will oxidise, and only a small amount of oxidation product is necessary to cause chemical fog. Therefore, when dissolving Elon, dissolve a portion of the sulphite first, sufficient to prevent the immediate oxidation, and yet not enough to prevent the Elon from dissolving readily, then dissolve the Elon, and finally add the remainder of the sulphite.

The alkali (say carbonate) may then be added:

(a) Dissolve the carbonate separately and add to the cooled Elon-sulphite solution. There is danger, however, of the Elon precipitating out before the carbonate is added.

(b) After dissolving a portion of the sulphite and adding the Elon, dissolve the remainder of the sulphite and carbonate together, cool, and add to the Elon-sulphite mixture.

The above procedure is necessary so that when the carbonate is added the solutions are cool. If a hot carbonate solution is added to the developing agent, even in the presence of the preservative, some substance is formed which produces chemical fog.

In the case of developers containing no bromide, used for testing the quality of plates, and for developing under-exposed negatives, it is absolutely necessary to mix the developer with cold water if a minimum of fog is desired.

In the case of some samples of paraminophenol which are discoloured by the presence of oxidation products, these may be partially removed by boiling after adding to the sulphite solution. In this way the oxidation products are reduced back again by the sulphite to paraminophenol, though the solution should be cooled again before adding the carbonate. If pure chemicals are used such a procedure is, of course, entirely unnecessary.

Bromides and iodides are added to a developer to compensate for any chemical fog produced by the developer, or inherent in the emulsion. It is immaterial at what stage the bromide is added during mixing.

When mixing a developer the following rules should therefore be followed:

1. *Dissolve the preservative first.* In the case of Elon dissolve only a portion of the sulphite first, dissolve the Elon, and then add the remainder of the sulphite.
2. *Make sure that one chemical is dissolved before adding the next.* If the alkali is added before the crystals of the developing agent are dissolved, each crystal becomes oxidised at the surface and the resulting solution will give fog.
3. *Mix the developer at as low a temperature as possible.*
4. *In the case of desiccated chemicals like sodium carbonate and sodium sulphite, add the chemical to the water and not vice versa.*

* This consists of methyl-paraminophenol base which is relatively insoluble, but in combination with sulphuric acid (Elon) it is readily soluble. When sodium sulphite is added to Elon the acid portion is neutralised and the difficultly soluble base is precipitated. The presence of acid may be shown by adding a little sodium carbonate to Elon when effereescence takes place. The reason why Elon does not precipitate with sodium carbonate is because the Elon base combines with it forming a sodium salt which is readily soluble.

Two practical methods of mixing are possible, as follows:

(a) Dissolve all the chemicals in one bottle or vessel by adding the solid chemicals to the water in the correct order (in the formula the ingredients should be named in the order in which they are dissolved). For example, to mix the following formula proceed as follows:

Sodium sulphite	75 Gms.
Elon	10 Gms.
Hydroquinone	5 Gms.
Sodium carbonate	50 Gms.
Potassium bromide	1.5 Gms.
Water to	1 Litre.

Dissolve about ten grammes of the sulphite in about 750 c.c. of warm water, and then dissolve the Elon. Now dissolve the remainder of the sulphite, and then the hydroquinone. Finally, add the carbonate and bromide, and dilute to 1,000 c.c.

For large quantities the filter-bag method should be used, the chemicals being placed in the bag and dissolved in the above order.

(b) An alternative method is to dissolve the preservative and developing agent in one vessel, and the carbonate and bromide in another, cool and mix. This method is the safest and best for quantity production.

For example, to mix the following motion picture developer, proceed as follows:

Sodium sulphite	4 lbs.
Hydroquinone	13 ozs.
Sodium carbonate	4 lbs.
Potassium bromide	3 ozs.
Water to	10 gals.

Dissolve the sulphite in about one gallon of hot water, then dissolve the hydroquinone, and filter into the tank. Then add one gallon of cold water to the tank, dissolve the sodium carbonate and bromide in one gallon of hot water, and filter this into the tank, immediately adding cold water up to ten gallons. The object of adding cold water to the tank before adding the carbonate is to cool off the solution before the carbonate is added.

Mixing Concentrated Developers.

The extent to which a developer may be concentrated is determined by the solubility of the least soluble constituent, because a stock solution should usually withstand cooling to 40° F. without any of the ingredients crystallising out. Usually, the hydroquinone and Elon come out of solution on cooling, but by adding alcohol (grain, wood, or denatured) up to a concentration of 10 per cent., the crystallisation is prevented, since the developing agents are very soluble in alcohol.

The addition of the alcohol does not prevent the other ingredients such as sodium sulphite from crystallising out; in fact, the alcohol diminishes their solubility, and therefore increases the tendency to come out of solution.

A paraminophenol-carbonate developer is difficult to prepare in concentrated form, though by adding a little caustic soda the solubility of the paraminophenol is increased and a stronger solution can be thus prepared.

When preparing concentrated developers it is important to observe carefully the rules of mixing, taking care to keep the temperature of the solution as low as possible if a colourless developer is to be obtained.

Two Solution Developers.

A two-solution developer is simply a one-solution developer split into two parts, one containing the carbonate and bromide, the other containing the developing agent and preservatives, so that the developer will oxidise less readily, and therefore keep well. The reason why it is customary to keep a developer like pyro in two solutions is because pyro oxidises much more readily than Elon or paraminophenol with a given amount of preservative.

For purposes of mixing only one solution developers need be

considered because the same rules regarding mixing apply in both cases.

Developing Troubles.

In order to be able to explain the reason for any particular developer trouble it is necessary to understand thoroughly what takes place when the ingredients are mixed in the wrong order or if any ingredient is omitted from the formula, and also the effect of chemical impurities. It is impossible in this article to indicate every possible trouble, but the more important ones may be listed as follows:—

1. *The Developer Gives Fog or Chemical Fog.*—Fog is the chief trouble caused by faulty mixing. It may be due to any of the following reasons: Violation of the rules of mixing, mixing the solution too hot, omission of the bromide, addition of too much carbonate or too little sulphite, the use of impure chemicals, etc. (See article on Chemical Fog above.)

2. *The Solution is Coloured.*—As a general rule the developer when mixed should be colourless, and if coloured the developer should be suspected as being liable to give fog. In the case of a pyro developer mixed with bisulphite which contains iron, the iron combines with the pyro to form an inky substance which imparts a dirty red colour to the solution.

If a pyro developer is mixed as two separate solutions A and B, the pyro B solution, which usually contains only carbonate and bromide, should be perfectly colourless, though if carelessly mixed in dirty vessels it may be coloured brown by the presence of a little pyro A.

3. *If the solution does not develop*, then either the developing agent or the carbonate was omitted during mixing.

J. I. CRABTREE.

(To be continued.)

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).
The Postcard Studio (March 14).
The Printing-Room (March 21).
About the Reception Room (March 28).

Home Portraiture (April 4).
Portable Studios (April 11).
Copying (April 18).
Handling the Studio Camera (April 25).
More About Lenses (May 2).
Enlargements (May 9).
Advertising the Studio (May 16).
Mounts and Mounting (May 23).
Business Methods (May 30).
Photographing Children (June 6).
Portraits of Elderly People (June 13).
Something about Lenses (June 20).
Hand Cameras for Professionals (June 27).

THE DARK-ROOM AND ITS FITTINGS.

WHEN we consider the amount of time which a photographer spends in his dark-room, it would be supposed that he would do his utmost to plan it so that the space at his disposal should be utilised in such a way that the work should be carried out in the most convenient manner possible, and that all unnecessary steps and movements should be avoided. But in many cases this is not done, and the room appears as if it had been fitted up by a builder without any knowledge of photography, and that he had placed the various fittings where he thought that they looked best, without reference to their use. To prove this I may instance one place fitted up only a few months ago in which the red lamp was placed immediately behind the operator, so that he was effectually prevented from seeing what he was doing when he stood at the sink.

The smaller the dark-room the more need for careful planning, and we might well take a lesson from the ship-builders, who manage to squeeze the maximum of accommodation into the minimum of space. In the first place, I would point out that in the majority of dark-rooms too much room is allowed for the operator and too little for the fittings. Let us take the case of a floor space of 6 ft. by 4, which we may consider the minimum (although I have often had to work in less), and see how we can plan it to the best advantage. If there happens to be a window in it, it should be ignored for lighting purposes, although it should be made to open easily for ventilation. This gives us a free hand for the placing of the sink. I should then arrange things in the following way. The doorway 2 ft. wide should be cut in one of the 4-ft. sides, preferably on the left hand. This must be well rebated so that in case of a slight

shrinkage no light will be admitted. A bench 2 ft. wide is run the whole length of the room, and in the centre of this a 36 x 22 Doulton or lead lined sink is fitted, leaving two solid pieces 18 x 24 at either end, these being covered with lead or ruberoid or well coated with asphaltum varnish. Lead is the cleanest and most durable, and should be used if the expense is not objected to. The red lamp should be placed over the left back corner of the sink and the water tap over the middle of the sink, not projecting too far forward. Across the further end of the room a plain bench 15 ins. wide is fixed between the wall and the long bench. This answers for filling-in or, if it be preferred, a printing-box may be installed here and filling-in done on that part of the bench which is just behind the door, the latter, of course, being made to open outwards. A narrow shelf for bottles and measures should be placed over the sink, and a shallow cupboard with the door hinged at the top fixed over the filling-in bench to receive exposed plates. The reserve stock of plates can be stacked on a shelf under the bench. The fixing-bath or tank is put on the bench to the left of the sink or, if preferred, on a shelf below it. I do not, however, care for this arrangement, as it is then difficult to avoid splashing hypo on the floor. A shelf or rack may be fitted over the end bench to receive spare dark-slides, inner carriers, and the like.

So much for the general plan. Now let us go into the details of the fittings.

As I do not know what illuminant will be available, it is not possible to give precise details as to the red lamp, so that it can only be dealt with in general terms. One thing is important, that it should be of adequate size. The minimum

frontage should be 10 x 8 and as much larger as convenient. This allows of a safe medium being chosen and still having a good working light. Now as to the medium: Some ruby glass is safe for use with rapid plates, but much is not, and the eye is not a safe guide. I have seen a very deep ruby which passed an appreciable amount of blue, while a lighter colour, such as that used in the old Perfection lamps, was fairly safe. For use with an oil light or carbon filament one thickness of ruby glass and one of canary fabric seems quite safe, or one thickness of orange glass and one of red fabric. The metallic filament lamps are more actinic, and if these are used it is better to use the Wratten or Lumière "safe lights," which are scientifically constructed so as to be quite secure against fogging. After all, the best way is to make a practical test with the plates it is intended to use. If a plate partly covered with a piece of metal—a penny will do—can be exposed in the position usually occupied by the developing dish for five minutes, and after development in a covered dish for the same period shows little difference between the covered and uncovered parts, the light can be considered as reasonably safe. For bromide printing a brighter light is required, and I have found that two thicknesses of canary medium bound up between glass give a safe light with any bromide paper I have used. If gas is used, the ordinary fish-tail burner is the best, as the light is yellow to begin with, but as some gas gives but little light when used in this way it may be necessary to use a small inverted mantle. With this a sheet of yellow glass may be added to the fabric. A single thickness of Perfection glass seems quite safe for bromide papers.

There is a certain amount of choice in the material of which the sink is composed; it may either be composed of wood lined with lead or an asphalt sheeting such as ruberoid, or, what I consider better, of stoneware. If the latter be chosen, it is very necessary that it should be of the hard vitrified quality which has a dirty yellow surface. This has no glaze to flake off, and will last until it is broken, which, I may say, is an unlikely contingency. There is a much nicer-looking quality which has a white glaze on the inside. This I have not found reliable, as the glaze is liable to crack, and when the chemicals begin to percolate into it the glaze comes off in flakes. Zinc or galvanised iron must not be used for sinks, as they rapidly corrode and become leaky. Slate is also a bad material, as it is likely to flake away, and, even if it does not, leaks are likely to occur at the joints. With any sink it is advisable to use a rather close wooden grid covering the whole bottom. This saves many breakages both of measures and negatives, and has the advantage of keeping the dishes out of the water which is always present, more or less, at the bottom of the sink. A trap with a screw plug should be fitted to the waste pipe, so that any obstruction can be removed without having to call in the plumber.

The question of dish versus tank development cannot be dealt with here, but a word on the materials of which dishes and tanks are composed may not be out of place. Porcelain dishes are most generally used, but they are heavy and fragile, and I strongly advise the use of a good make of enamelled iron in their stead. Even these require a certain amount of care in use, but it is surprising how many falls and knocks they will stand without chipping. Good vulcanite dishes are also very serviceable, but they are costly and not now easily procurable. Celluloid dishes are only useful for very occasional use; even the best of them are very apt to crack at the corners, and there is also a tendency for them to warp, often to an extent which renders them useless. Wooden dishes are convenient when large numbers of plates are dealt with, but it is difficult to find a coating which will resist the alkali in the developer. I used some, many years ago, of American make which stood very well, but I could never discover the composition of the varnish. Possibly gas-tar diluted with naphtha, which was recommended

for the purpose by Mr. F. A. Bridge, would do, but I cannot speak from experience. I have tried shellac with an alkaline developer, and the wood was bare in a week. Tanks for developing and fixing are steadily growing in popularity. The amateur tanks made of brass or zinc are of little use to the professional who does not want to develop in daylight. Good wooden tanks with loose racks seem to answer well, and a later model, with an enamelled tank and a wooden rack, seems better still. The ordinary porcelain tanks are not suitable for development, as they require an enormous bulk of solution in proportion to the plates they hold. Such tanks are, however, useful for fixing, if one is careful not to drop the negatives in too suddenly, when either plate or tank may suffer. On the whole I prefer a stout lead-lined tank for hypo. Washing tanks are best made of plain zinc; the white japanned ones look clean, but unfortunately they are made on a base of sheet iron or steel, and once the protective coating is damaged corrosion goes on apace. One advantage of a zinc tank is that it can be cheaply repaired. I have one half-plate tank which has now its third bottom; the others have been rubbed through. The sides and grooving are strong and good after twenty-five years' wear.

A little point I had nearly forgotten is that of taps. The swing-arm tap is attractive to look at, but it quickly goes wrong, and when it becomes leaky it is difficult to repair. A good ordinary tap with an anti-splash, to which a short length of rubber tube can be attached, is the most practical arrangement. It is a good plan to have an extra tap to supply the washing tank, so that plates do not have to be rinsed over the tank. If there is only one tap the rubber tube can be lifted out of the tank for rinsing purposes.

Last, but not least, comes the question of ventilation. We must not trust to badly fitting doors and partitions for this. A proper inlet and outlet for air must be provided, or the operator's health will suffer. I have found it answer well to have a row of inch and a-half holes, well trapped, made in the partition below the sink and another similar row on the same side near the roof. With this arrangement a current of air is always passing just where the operator usually stands. Care must be taken not to block the inlet with boxes, tanks, or the like. If it be possible to fit an exhaust fan, worked by electricity or water, in the dark-room, by all means do so. It is a luxury in hot weather.

Although I have only specifically described a very small dark-room, it does not follow that such a size is a desirable one, and the larger ones, besides being more comfortable to work in, allow of more fittings, such as enlargers, being placed therein; the principle is the same: as much sink-room as you are ever likely to need and plenty of benches. Do not use the dark-room as a store for lumber. A small, clear space is better than a large one in which you have no room to turn.

PRACTICALS.

FORTHCOMING EXHIBITIONS.

September 13 to October 11.—London Salon of Photography. Entries close September 2. Hon. sec., 5a, Pall Mall East, London, S.W.1.

A FIRE broke out at 2.15 a.m. on Sunday at the premises of Mr. J. Reuben, 241, Old Kent Road, S.E., photographer. About 6 ft. by 4 ft. of flooring and joisting was damaged by fire and cutting away in the shop, whilst the contents were slightly damaged by smoke.

AERIAL PHOTOGRAPHY.—With regard to the possibilities of stereoscopic photography in charting unsurveyed country, Mr. Holt Thomas, at the London Society last week, said that a single aeroplane had in one flight completely covered with photographs an area of 40 square miles. The cameras used for this work were quite automatic, and once started would go on taking photographs of whatever was under them, without any attention until the film was used up.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

The Man and the Job.

AMONG my photographic acquaintances are two who, for the time being, I will call Smith and Jones, for the simple reason that those are not their names, or anything like them.

Smith and Jones are living examples of how and how not to treat one's employment.

Jones is a pessimist; he reckons photography in general, and his own job in particular, as decidedly "N.G." He is always on the move, and his moves are vague and indefinite. This is because Jones has no forethought; his moves are usually precipitated by that fed-up feeling, and his moving places found by an orgy of letter writing in reply to advertisements.

This necessitates a preliminary and frantic search for the current "B.J."—I know, because he's borrowed mine at times—for Jones is a chap who has no time for reading (and if he had he'd probably pooh-pooh everything he read).

Smith is also a wanderer—or used to be—but of a different sort. Smith moved about because it pleased him to, and he moved just when and where he liked. The consequence was, he acquired a broad experience and saw some life, believing in that old proverb, "A rolling stone gathers polish rather than fungi."

Now, how did Smith manage to move when and where he liked? It was due to a combination of circumstances, which I will try to explain. In the first case, he was a very observant person. He studied his trade journal, and so was always up to date, and always knew the state of the labour market. I remember him saying once that his best appointments had been obtained when he least needed them, which means that if he hadn't sought them until they were needed he wouldn't have got them.

When Smith arrived in a new town, the people in the place he went to work for were not the only ones who knew it. Quietly and without ostentation he would introduce himself to every photographer in the place. "Nothing like being known," he would say, and certainly his sociability was at times of advantage—to others as well as himself. He could inform one on so many studios and workshops that it was odds on that any vacant post could be correctly gauged by applying to Smith.

Although he left so many jobs, he reckoned to have always exhausted a position's possibilities before turning it down. This is where many workers fail. They contemplate a move without first asking, "Am I better off for the future where I am?" If not, that is when the place is absolutely worked out as far as improvement goes; then it is time to move, but not before—unless for something extra good. While a post has monetary or educational value it is worth making the most of.

The Smiths of photography never leave such jobs without precise deliberation. How do they keep them and always manage to go up when they leave?

Geniality and business instinct have a lot to do with it; skill and reputation go a long way, too; they should all be cultivated. The genial man—not too genial, by the way—has a big hold on his boss and his fellow workers; he will be considered when the grouser is forgotten or wished away. The pleasant chap, coming like a sea breeze or a ray of summer sun into a strange studio, will obtain a vacant post where a pessimist would not.

Business instinct will save the genial employee from being swindled, put upon, or made a "willing horse." When "up against" anything, the unbusinesslike worker may use "language" or may walk out quietly; the businesslike one will firmly point out his side of the case and politely insist on his rights. Ten to one he wins every time.

A great deal of Smith's success was due, I think, to his skill

and the way he used it (sounds ambiguous, but I will explain). He acquired, by hard work and study, almost specialist skill in a good many distinct lines. When he wanted a change he was not tied down to a chance in any one branch. If no operators were wanted, well, perhaps retouchers or enlargers were in demand, and so he always had multiple chances. But he never went as a G.K.C., as he would term the all-round man. Now, Jones was a typical G.K.C. (general knockabout comedian), with a smattering of all branches of photography but without the ability to get the wages of a good exponent of any one line. If Smith was engaged as an operator, he kept within his agreement and studiously avoided the printing department. If asked to undertake more than one job, he was agreeable only if the matter was on a business footing and the pay adequate.

Although Smith left a few employers much against their wishes, he managed to save his reputation. He could always mention a firm who would willingly recommend him for some particular work, and if asked he could always show a good reference and specimen in keeping with a new shop's requirements.

Personally, I don't believe in carrying references or specimens. The former are often "tommy rot," and the latter are "acquirable." I travelled long and far without ever showing one or the other.

Reputation, though, is a serious factor, and whether we carry evidence or not, the facts can be rooted out. Therefore, one must have a good reputation. If through misfortune things are otherwise—a worker's reputation goes when he is known to have been in a cheap or shady firm, even though his character be irreproachable—then one must do without a reputation altogether until a new one can be built. A knowledge of the world photographic will simplify this.

The wise employee will never leave a nasty taste behind him. I know it's nice to tell a man a few coloured facts now and then—I've done it—but in after years that man may have something of benefit for us, and the coloured facts may rise and bar the way.

Every employer a workman knows should be looked on as a link in the workman's connection, just as the owner looks on his sitters. Every link is useful, and should receive intelligent consideration. The fact of not being able to work for a certain man does not mean that that man is no use.

A few hints in conclusion: When writing to a stranger be polite, businesslike, and concise, but not curt or snappy. In studying his reply, don't overlook the style, phraseology, and writing. They tell quite a lot, as a rule. Place your inquiries deliberately, not at random. For instance, if you want an operator's post in, say, Birmingham, advertise the fact. Also watch the "B.J." Plenty of adverts. appear for Birmingham, but they don't pop up to order at the critical last moment. The Birmingham daily papers—taken by all city libraries—are also worth watching. If you know any photographers in the district inquire of them.

A craftsman who has a particular penchant for any make of paper or plates should get to know the representative of the commodity. Many a master and man have been united by the kindly—though, of course, unofficial—offices of the "man of the road."

It sometimes happens that an excellent opening occurs in a line that one has no practical experience of. To take it or not is a difficult thing to decide, and must depend on the man himself. I remember, when war broke out, being asked to undertake some very important work, the nature of which—though photographic—was totally foreign to me. I decided to chance it, and succeeded by sheer bluff, until I had gained sufficient working knowledge to carry on. I never regretted my decision, but must admit it was sailing close to the wind. Had I been found incompetent it would have meant disaster so far as that work and my reputation were concerned. Much assistance was gained in this case from the "B.J." and a couple of handbooks. For the observant craftsman, however, there are always openings without undue risk, and the cheerful, confident individual need fear nothing worse than a fall on his feet if he only keeps up-to-date and wide awake.

Granted that wages and general conditions are as yet unstandardised and unsatisfactory, it is still possible to keep going toward better times.—THERMIT.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JULY 6.

Manchester Amateur Photographic Society. Outing to Wilmslow.

MONDAY, JULY 7.

South London Photographic Society. Print Criticism Evening.

TUESDAY, JULY 8.

Manchester Amateur Photographic Society.—Monthly Meeting.

Hackney Photographic Society "Northern Europe." Dr. C. Atkin Swan.

THURSDAY, JULY 10.

Rodley and District Photographic Society. Monthly competition: "Summer Hambles."

Hampshire House Photographic Society. "Toning." G. Hawkins.

CROYDON CAMERA CLUB.

LAST week Mr. T. W. Purkis was down for an evening on "Stupendous Stunts," a title not his own. Prior to starting the stunts, votes of thanks were accorded all who had helped to make the Affiliation outing a success, with special reference to the secretary, Mr. J. M. Sellers, who had worked like a horse. The president, Mr. J. Keane, in an outburst of oratory, referred to the secretary's achievements as of "outstanding and staggering significance."

Of the many capital stunts executed by Mr. Purkis, reference can only be made to a few having some connection with photography. The first shown was a neat way of weighing small quantities of chemicals without contaminating them by contact with a possibly dirty pan. The little corrugated papers used for chocolates were employed, one for receiving the chemicals to be weighed, the other as a counter-weight. They are sold at 1s. 6d. a thousand (No. 3 size), and may be procured from Kettles, of New Oxford Street.

The next tip was a method of simultaneously dissolving and filtering chemicals not readily soluble. A large glass funnel is placed with its tube in a bottle of sufficient size, and a pledget of cotton-wool is rammed down into the funnel, so that water placed in it only emerges drop by drop, the rate being regulated by the degree the wool is compressed. This can be ascertained by adding water before starting, which is thrown away after the test. The chemical to be dissolved is placed on the cotton-wool and the requisite quantity of water carefully poured into the funnel, whereupon a short holiday can be taken, with every assurance that solution is proceeding satisfactorily in one's absence. A fair quantity of the cotton-wool seemed to have drifted into the president's brain box judging from the questions he asked, but the idea ultimately filtered through in pristine clarity.

A really capital levelling-slab followed. It is made by taking a sheet of thick plate-glass and attaching at each corner a leg of "plasticine" about one inch high. With a spirit-level placed on top, the glass is pressed down in directions indicated by the bubble, until a perfectly level surface is obtained. If the table is to be used for heavy things, considerable pressure must be given; for light things less pressure, naturally, suffices.

During the war the lecturer had occasion to coat very small discs with collodion emulsion, and found the table most useful as a setting slab. When coating, he dispenses with any form of pneumatic holder, which often records its form in the emulsion, probably due to the circular strain induced in the glass. Instead he uses some hectograph jelly, on top of a rod of glass, for very small discs. For coating glasses of large size up to 10 x 8, he attaches with secotine a quarter-plate glass to a wooden holder, and then applies small pieces of the sheet jelly to the four uppermost corners, which in turn hold the large plate. The correct formula for the jelly aroused fierce controversy, and at one time it appeared inevitable that blood would be shed. With all reservation we give the lecturer's recipe:—Soft gelatine (Nelson's No. 1, O.K., but expensive), 1 oz.; treacle (if you ask for treacle you will get golden syrup, which is right), 8 fl. oz.; water, 5 oz.; 10 per cent. carbolic in alcohol, 1 fl. dr. Proceed as usual (no directions for mixing were given).

The next exhibited a whirler improvised out of an egg-whisk, introducing anxiety in his neighbours when he coated a held glass

with fish-glue solution. Excess was, however, whirled off by placing the glass, coated side down, in a large tin, and nobody suffered. A simple and novel spectroscope now shown was based on the principle of edging a piece of discarded Thorpe replica grating, but as Mr. Thorpe has been unkind enough not to answer the last letter of request, a detailed description seems unnecessary. The instrument rattled horribly when moved, but this did not impair its efficiency, a fine spectrum of the first disorder being secured. Finally, Mr. Purkis drew attention to a small soldering iron fitted with an automatic blowpipe, which, in his hands, kept the iron at a cherry-red heat. A most hearty vote of thanks was accorded the "stupendous stunter" with great acclamation.

Photo-Mechanical Notes.

The Imitation of Wood on Metal.

A GOOD deal of metal furniture is now being sold which resembles wood—for example, desks, filing cabinets, cash registers, etc. In some cases this is painted by hand, the graining being done in the way made familiar by the house painter. Needless to say, this is not particularly faithful, and the first improvement consisted in taking a selected plank showing a fine specimen of grain, cleaning it thoroughly, covering it with a suitable ink, squeezegeeing off the excess, which leaves the compound only in the grain, then rolling over this with a composition roller of a circumference large enough to cover the metal sheet to be grained, then off-setting from the composition roller to the metal plate, baking, varnishing, and the graining is finished. This method depends on the fact that the grain is produced by differences of surface, but it does not give you any of the effect light may have on the grain independent of surface. For instance, in an oak, the big, flat grain will always appear white by this method, whereas in really good wood, if looked at in a certain way, these white patches of grain have a dark centre, which is not due to any differences of level of surface, but to the play of light. Now, all these delicate differences can be reproduced by photography, using, of course, suitable lighting, proper colour-filters, and a panchromatic plate. A half-tone negative is made, and from this a print on metal, which can be transferred by means of the composition roller; or the plate may be etched if any improvement is required to be done by fine etching before the transfer is made. But perhaps the best effect of all can be obtained if a half-tone positive is made and from it a lightly etched intaglio plate, which is inked up, and the transfer taken from it.

Do not Tinker with your Engravings.

THE chief source of error in making engravings is incorrect instructions, or correct but insufficient instructions which leave room for misunderstanding. The fault lies here with the office, who if the instructions given by the customer are vague, should get them definitely before passing the work out to the shop. On the other hand, the shop foreman should ask the office for definite instructions if they are not given. But when a mistake has been made, to whatever it was due, it will generally be found cheaper and more satisfactory, to find out the point where the mistake occurred and commence over again from there rather than tinker with the work in an endeavour to rectify the error on the finished job. If there is one thing more than another that has retarded the progress of three-colour work it is the possibility of asking the fine-etcher and engraver to rectify all the faults in the process. Had it not been for this we should long ago have had three-colour results just as possible mechanically as are black-and-white results, for we should have been forced to use correct filters and plates, to give correct exposures, and to insist on truly complementary inks. But anything does now, because, however gross the error, it can be patched up by the re-etcher, expensive and more or less unsatisfactory as the system. What is so plainly true of three-colour is also true of ordinary half-tone, and even line work. It usually costs more to patch up mistakes than it costs to start the work over at the point where the error crept in, and is less satisfactory in the end.

Retouched Originals in Half-Tone Work.

A freshly retouched original that is well done is a delight to the operator to handle. But the retouching is not always well done from the point of view of the photographer, and one of the most difficult lessons for the retoucher to learn is to know how the colours he uses are going to photograph. Generally speaking, it is quite unsafe to use any other colour than one that matches the photograph that is being retouched; for example, it is a mistake to use a brown on a black and white print. Retouching is expensive work, and the customer is apt to put a limit on the money he is willing to spend, and therefore the retoucher cannot do exactly as he would like; but he should be careful that if he touches certain tones in the photograph he should touch all of them, as otherwise the retouching is very likely to reproduce differently from the photographic image itself, with unfortunate results. This is particularly true of the deep shadows. The retoucher will sometimes strengthen up some shadows and assume that others on the print are strong enough, but in the reproduction the one may come out black and the other grey, and so upset the whole value of the picture. However good the retouching, it usually deteriorates with age, so that if any old originals are to be re-photographed they should be carefully looked over first. The photograph itself is likely to have faded, and so makes the contrast with the retouching entirely wrong. Any Chinese white on the print will probably have become yellowed, and some of the blacks, particularly if the paint has been mixed with gum, will probably have chipped off. Some insects appear to have a peculiar fondness for the pigments used by retouchers, and if the originals have been stored where these pests are they will be found to require considerable attention before they can be re-photographed.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, June 16 to 21.

CINEMATOGRAPHY.—No. 15,259. Cinematograph screen. T. Cooper and A. Slater.

CINEMATOGRAPHY.—No. 15,088. Winding apparatus for cinematograph picture films. H. Dixon, F. C. Jessett.

CINEMATOGRAPHY.—No. 15,252. Cinematographs. G. Lynch.

CINEMATOGRAPHY.—No. 15,547 and No. 15,548. Cinematograph screens. W. J. Marks.

COLOUR CINEMATOGRAPHY.—No. 15,549. Method of adding colour to cinematograph pictures. W. J. Marks.

CINEMATOGRAPHY.—No. 15,550. Mobile cinematograph outfits. W. J. Marks.

PHOTOGRAPH FRAMES.—No. 15,142. Photograph frames. W. P. Winsor.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

COLOUR CINEMATOGRAPHY.—No. 126,220 (August 14, 1918). The invention relates to a system of colour cinematography in which six successive different colour selections are made. Three of these are red colour-sensations, and are alternately arranged; of the other three, one is green and the remaining two are primary colour selections other than red. In consequence of the length of the specification, the details of the process are transferred to the Colour Photography Supplement published with this issue. Joseph Shaw, 8, South Second Avenue, Mount Vernon, New York.

WATERPROOFING FILM SPOOLS AND PACKS.—No. 116,882. May 12, 1919. The aim of this invention is to produce a self-contained cartridge, pack, or other multi-exposure film package, which

without a separate container shall be hermetically sealed, waterproof, and capable of withstanding for long periods even immersion in water, thereby greatly prolonging the period within which the film may be satisfactorily exposed and developed, and guarding the same against injury by mishaps before or after exposure, which under present conditions would utterly destroy their usefulness.

The stated ends can be attained by first hermetically sealing all openings through which moisture might possibly enter within the photographic cartridge, pack, or package, and thereafter immersing the whole in a bath of waterproofing material, or otherwise completely coating its exterior with such material.

Under the construction now generally adopted, the end of the outer wrapper or envelope is V-pointed, and held down upon the body of the cartridge by a sticker or paster, which is carried around the cartridge either completely or partially. Under the new construction, this pointed end is folded back within the wrapper, and instead of a paster or sticker covering the meeting line of the free end and the body of the wrapper or envelope for a portion only of its length, a waterproof strip or band of or coated with adhesive materials is employed, which extends from end to end of the fold or joint, and hermetically seals the opening between the free end and body portion of the wrapper or envelope. At each end of the cartridge is applied a strip or band of like adhesive waterproof material, pressing the same down into firm and close contact with the outer and inner faces of the discs, and causing the inner edges of the strips to overlap and adhere to the sealing strip or band and to the wrapper or envelope, if the same be not completely encircled by said sealing strip or band.

As the discs are somewhat lightly pressed to place upon the shouldered ends of the spool, there is a possibility of moisture entering at these points. Effectively to guard against this, the entire exposed or outer surface of the cartridge, pack, or package is coated with a waterproofing agent in the form of a liquid solution, either by brief immersion therein or by applying the same by brush, spray, or otherwise. Cellulose acetate, cellulose nitrate, or like cellulose derivative is admirably suited to this purpose, these being capable of being made as thick or thin as desired, and being also thoroughly waterproof.

In its essential features the mode of waterproofing the film pack is the same as in the case of the cartridge; that is to say, the openings of the light-excluding wrapper or envelope are first sealed by strips of adhesive, waterproof tissue of fabric. Thus strips are applied to and made to overlap the longitudinal boundaries of the opening on the lens side of the pack, the strips being caused to adhere to the body of the envelope and to the light-excluding sheet, which, as the pack is furnished to the trade, closes such opening. Other strips similarly cover and seal the transverse edges or the ends of the opening of the front or lens side of the pack, and the entire ends, front and rear, of the pack. At the tab end of the pack where the tabs of the individual film-moving strips or envelopes are folded down upon the exterior of the pack, the strip is carried over and somewhat beyond said tabs, and cemented to the back of the light-excluding wrapper. After being thus sealed, and to guard against any possible opening remaining, the entire pack is immersed in or otherwise coated with a film of cellulose nitrate or other waterproof cellulose derivative.

The cartridge or the film pack prepared as above described does not require the usual outer wrapper of coloured paper and metallic foil, nor the paper or cardboard envelope, though either or both of these may be retained if desired.

The film may after exposure and development be re-wound upon its spool or support with the waterproof wrapper and envelope, and resealed hermetically by the adhesive strips or bands removed at the time of placing the cartridge, pack, or package in the camera, these being preserved for such subsequent use or reapplication. This is particularly desirable for explorers, travellers, and commercial photographers, who are frequently away for long periods without facilities for properly protecting or caring for films under customary conditions of use. Arthur Williams McCurdy, 83, Crescent Road, Rosedale, Toronto.

Commercial & Legal Intelligence.

A PHOTOGRAPHER'S FAILURE.—At the offices of the Official Receiver for the Croydon District, York Road, Lambeth, S.E., on Tuesday last, the first meeting of creditors was held under the failure *re* Theodore Frank Newman, of 2, Anerley Park, Anerley. The statement of affairs filed by the debtor showed gross liabilities amounting to £712 4s. 10d., of which £695 7s. 4d. was due to unsecured creditors. The assets consisted of cash at bank, 10s., and interest in patents and on contracts, £1,300, making a total of £1,300 10s., from which £16 17s. 6d. had to be deducted for the claims of preferential creditors payable in full, leaving the net assets at £1,283 12s. 6d., and showing a surplus of £588 5s. 2d. after payment of all debts. The debtor alleged his failure to have been caused through the stoppage of the demand for scientific films and stoppage of his research work owing to the war.

The Official Receiver's report upon the case was to the following effect: The receiving order was made on a creditor's petition, the act of bankruptcy being failure to comply with the requirements of a bankruptcy notice.

The debtor, aged thirty-three, stated that after assisting his father in his business of a photographer he worked from 1906 to 1909 as an assistant to firms of colour cinematographers.

In 1910 he commenced business on his own account at Harlington as a producer of scientific films, with a capital of £50, representing savings; he subsequently removed to the Rookery, Watford, then to the Haven, Merstham, then to Cricklewood, and in December, 1918, to No. 2, Anerley Park. From May, 1918, to November, 1918, he was employed by an aviation company as works chemist at a salary of £7 per week.

He first had recourse to moneylenders on February 8, 1917; since that date he has obtained further loans from other moneylenders at high rates of interest.

From October, 1918, to February, 1919, he patented inventions relating to sparking plugs for aeroplane engines and to a safe memo refill for pocket books; he also invented a process for purifying the air in telephone cabinets.

On May 30, 1919, he entered into an agreement for the sale of his interest in a rust-proofing invention for £250 cash, which he has received, and £500 fully paid in shares in a company to be formed within six months from that date. His services were to be at the disposal of the purchaser for a period of five years at a fee of £2 2s. for every day upon which he was employed; the company has not yet been formed.

For the past two years he has been under continual pressure from his creditors, and since March, 1918, actions for debt have been brought against him, and judgments obtained, by nine of his creditors, representing a total sum of about £330; one moneylender issued a writ for £80 against him on April 5, 1919, obtained judgment, and instituted the present bankruptcy proceedings.

The debtor did not keep any books of account. At his preliminary examination he stated that his assets were of uncertain value, and that he first knew he had not sufficient property to pay his debts in full about two years ago, when he had to borrow money from moneylenders to pay rent and other outgoings. Mr. Fredk. Seymour Salaman, chartered accountant, of 1 and 2, Bucklersbury, E.C., was appointed trustee.

NEW COMPANIES.

TUTILL, LTD.—This private company was registered on June 18, with a capital of £5,000 in £1 shares. Objects: To acquire the business of showcard manufacturer, gold-blocker, and photographic dealer. The subscribers (each with one share) are:—A. G. Tutill, "The Thorns," Preetwich Park, Manchester, showcard manufacturer; R. Hirst, 48, Livesey Street, Levenshulme, Manchester, bookkeeper. Directors to be appointed by the subscribers. Solicitor: W. Proctor, 36, Hrazzenose Street, Manchester. Registered Office: 9, Swan Street, Manchester.

FOTOCO, LTD.—This private company was registered on June 25 with a capital of £10,050, in 10,000 preference shares of £1 each and 1,000 ordinary share of 1s. each. Objects: Photographers, etc. The subscribers (each with 300 shares) are: A. J. Dreydel, 36, Primrose Mansions, Prince of Wales Road, Battersea, S.W.11.

gentleman; F. C. V. Laws, 10, Yarell Mansions, W.14, photographer; C. F. Lee, C.M.G., Finsbury House, Bloomfield Street, E.C.2, gentleman. Directors: A. J. Dreydel, F. C. V. Laws, and C. F. Lee, C.M.G. Registered office: Finsbury House, Bloomfield Street, E.C.2.

PHOTOGRAVURE CO., LTD.—This private company was registered on June 18, with a capital of £1,000 in £1 shares (750 pref.). Objects: To carry on the business indicated by the title, and that of printers, stationers, publishers, advertising agents, etc. The subscribers (each with one share) are:—F. T. Corkett, Butter Hill House, Dorking, art publisher; P. Lacroix, 21, Farringdon Avenue, E.C.4, photogravure plate engraver. Directors: F. T. Corkett, P. Lacroix, and C. H. Crabtree. Solicitor: E. Betteley, 23, Surrey Street, W.C.2. Registered Office: 21, Farringdon Avenue, E.C.4.

JEROME, LTD.—This private company was registered on June 20, with a capital of £50,000 in £1 shares. Objects: To acquire all or part of the businesses of B. A. Gale, Gale's Studios, Ltd., W. Smith and Bayley's Studios, Ltd., and to carry on the business of photographers, dealers in cinematograph machines and films and photographic apparatus, film renters, picture theatre proprietors, etc. The subscribers (each with one share) are:—B. A. Gale, Glentwood, Hale, Cheshire, company director; W. Smith, 3, Granville Mansions, Shepherds Bush, W., company director. The first directors are B. A. Gale and W. Smith. Solicitor: J. G. Mahaffy, 29, Blackfriars Street, Manchester. Registered Office: 45-7, Oxford Street, Manchester.

PHOTO BUTTON PLATES AND ACCESSORIES.

To the Editors.

Gentlemen,—I have a Cannon camera, and find great difficulty in obtaining photo button plates for this machine that are reliable as regards speed and uniformity of result. A tube of buttons often shows plates are a mixed batch, some requiring, even in bright sunlight, about five seconds exposure and others only two or three seconds. This, of course, quite upsets the operator's judgment and causes, on an average, 50 per cent. failures; and slow exposures are a nuisance. These plates are collodion, not so good as pre-war, and three times the cost. At Epsom recently I saw another operator of a Cannon camera who had some gelatine emulsion button plates, grand to work, quick snap in sunlight, half a second exposure in the shade. He said they were American plates, pre-war stock, and he could not get any more. We made a comparison test of the plates, used his developer in my machine, same light and distance and similar camera; results very different. He took me in about half a second and obtained a good picture. I took him with half second exposure and again five seconds, by watch; the first was no good at all and the second only passable. We tried again with my developer, with similar results.

The essence of successful button, brooch, and ferrotype (while-you-wait) picture business is a quick and reliable plate, one to catch your customer (or victim) while he or she "thinks about it." It's no use saying "Your photo in one minute, miss," if you have to take five minutes or more to do it. Cannot British makers compete with American, Danish, Norwegian, or German firms? The chance for British trade is *now*. Wake up, England; you are asleep (or dozing) in many industries to-day. I have written to many firms who do metal brooch stamping and the like to supply me with brooches and stands for button photos, and also to card and mount manufacturers, but get all sorts of excuses, such as "not their class of work," "men not demobilised yet for this special work," "can't spare the time," etc., and I myself want thousands if I can get them for peace time novelties for street ferrotype workers.—Yours faithfully,

F. WHEELDON.

239, Sherrhall Street, Walthamstow.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

S. M.—The firm manufacturing sensitive ferrotype button plates here is the Quta Company, 252/256, Haydons Road, Wimbledon, S.W.

P. McN.—The mercury vapour lamp if of the gridiron pattern would certainly minimise the defects you complain of; it would also give more illumination. We cannot say what difference in exposure there would be, but in any case it would not be unduly prolonged. No alteration of the focussing would be necessary.

D. R. H.—The only way you can secure flatness in the cards is to take them down before they are quite dry and put them under light pressure. In this weather it would be advisable to put them in a 10 per cent. formaline solution for a few minutes, then rinse before hanging up. This will greatly reduce the danger of sticking together.

H. E. G.—We do not know the album to which you refer. Messrs. Johnson and Sons, Union Street, Southwark, London, S.E., make several forms of loose-leaf albums and other books, and might have something to suit. They make for the trade only, so that if they could supply you, you would have to order through a dealer or stationer.

O. and S.—For throwing down silver from hypo baths you require to use strong solution of liver of sulphur (potassium sulphide). If you write to Messrs. Johnson and Sons, Ltd., 23, Cross Street, Finsbury, E.C., they will send you a circular of instructions of the best way to throw down the silver and of preparing the precipitate for the refiner to deal with.

E. H.—I. We do not know where the thin tin can be obtained, but probably any tinplate worker could get it for you. We do not think, however, that it would be satisfactory for masks, as it would be very difficult to get it to lie flat. Tinfoil is used by many of the postcard firms, but we think you would find that the orange celluloid supplied by Messrs. Kodak, Ltd., Kingsway, W.C.2, for this special purpose more convenient.

W. G. A.—I. The safest and best way of cleaning lenses is to apply one or two drops of absolute alcohol with a soft piece of silk, but be careful to keep it away from the blacking of the lens cells. 2. We have never seen a blue stain from P.O.P. They are usually yellow; then they are, of course, very injurious. 3. So long as the bath fixes the plates quickly, say, in five minutes, and does not stain the films, the colour does not matter.

A. T. C.—The spots are due to over-washing in a warm temperature. Half an hour, with frequent changes of water, is ample in this weather. With regard to the quinine, it must be understood that the action is optical only, and that any other similar granular coating would have answered as well. Except in an emergency, the ordinary backings of red or black would be superior. There is no advantage to be gained by backing a film, since this is so thin that halation does not occur.

FOCAL LENGTH IN ENLARGING.—In a fixed distance of 34 ins. from negative to paper, can you say, please, what focal length of lens would be required to enlarge from approximately $3\frac{1}{4}$ by $2\frac{1}{4}$ ins. to $5\frac{1}{2}$ by $3\frac{1}{2}$ ins.? Also, what minimum of camera extension would be necessary to use in such a case?—RALPH.

An eight-inch lens will give you the desired enlargement, with the negative and paper fixed 34 ins. apart, the camera extension with a rapid rectilinear would be as nearly as possible $12\frac{3}{4}$ ins. from negative to diaphragm.

W. G. A.—Metol, metabisulphite, hydroquinone and amidol should be kept dry. A convenient strength for soda sulphite and carbonate of soda is a 15 per cent. solution—that is, 3 ozs. dissolved in warm water and made up, after the crystals have dissolved, to 20 ozs. with water. Potass. metabisulphate is not very soluble. We should make it up in a 10 per cent. solution—that is, 2 ozs. dissolved in cold water and made up to 20 ozs. No objection to enlarging a negative that has been reduced, although very often, if it has been reduced with Farmer's reducer, its quality is not so good for enlarging.

C. H.—The following is used for tank development:—Metol, 30 grs.; hydroquinone, 80 grs.; soda sulphite, 6 ozs.; soda carbonate, 560 grs.; potass. bromide, 10 grs.; water, 80 ozs. Dissolve in the order given. This stock solution is double strength and requires to be diluted with an equal bulk of water for use. As the developer becomes weaker it may be strengthened with the undiluted solution. The developer will keep in the tank for a fortnight, after which it should be thrown away. Development should be complete in twenty minutes; when more time is needed the solution must be strengthened. The above quantities are for one gallon of dilute developer.

W. R.—If you have a folding focal-plane you must have the lens in a sunk mount. There is no other way of focussing. On the other hand, in a reflex there is no object in having the focussing mount except for the sake of a little extra extension, but with almost any reflex that we can think of there will be disadvantages which more than set off any advantage, chiefly the fact that very often the lens, if in a focussing mount, will foul the mirror. For general outdoor Press work, the folding focal-plane is used almost exclusively; it is rare to see a Pressman with a reflex, and we think that their choice is quite a good one, since with experience in focussing the folding focal-plane is much the handier and more efficient of the two types.

SUMMARY.

M. L. P. Clerc has worked out mathematically the conditions for the correction of an aerial negative taken obliquely to one taken vertically from the same view-point. (P. 396.)

Mr. J. I. Crabtree, in the instalment this week of his paper on the preparation of photographic solutions, deals chiefly with the making of fixing baths, and gives working instructions in an operation for which, in our experience, such instructions are much needed—namely, the compounding of the fixing-hardening bath of hypo, alum, sulphite, and acetic acid. (P. 393.)

In a contributed article Mr. C. Brangwin Barnes has some advice to give on the making of negatives for view postcards, urging the production of technically better negatives and the choice of a greater variety of subject for a given district. (P. 395.)

In his article this week "Practicious" deals with the choice and use of dry-plates from the standpoint of the portrait photographer, advising the use of a plate, whenever possible, considerably short of the maximum speed and of still slower plates when the working conditions permit. (P. 391.)

The camera of vest-pocket size, while not capable of replacing the ordinary half-plate and larger instruments, may nevertheless render useful supplementary service in outdoor and indoor photography of the "commercial" kind. There is little advantage in fitting a lens of larger aperture than $f/6$: a roll-film camera has the merit of being ready for instant use and of allowing a practically unlimited supply of sensitive material being taken. These and some further hints on the professional use of the vest pocket camera will be found in a leading article on page 390.

The great development of scientific industries, among which are photographic materials and photographic lenses, is shown by the exhibition of British Scientific Products which remains open at the Central Hall, Westminster, until August 5. (P. 399.)

The manufacture of the emulsion-coated transfer paper sold as Kerotype is the subject of the specification included this week in Patent News. (P. 400.)

A real summer temperature may have its effect in the dark-room in the way of thick and foggy negatives due to the higher temperature of the developing solution. (P. 399.)

Deterioration of the glass surfaces is a change to which many lenses, particularly some of the older anastigmats, are liable. It is a wise rule to keep lenses in tightly closed cases when not in use, or at any rate to provide a close-fitting cap for each end. (P. 389.)

A method of quickly ascertaining the exposure in enlarging has recently been described by a writer in an American contemporary. (P. 390.)

A few hints on the making of cloud negatives will be found in a paragraph on page 390.

EX CATHEDRA.

Heat Fog. Although at the moment of writing there is a decided drop in the temperature, it may not be amiss to refer to a point which has come under our notice several times lately. Complaints have reached us of plates which had previously yielded bright images giving thick, foggy ones. This is in the majority of cases due to the high temperature of the developer, and is more likely to occur when the developer is kept ready diluted in bulk in the dark room, where it rapidly attains the temperature of the room, which in some cases has been over 80° F. Even when stock solutions are diluted immediately before use, the trouble may occur through the water becoming heated in the pipes. This happened in one case only with the first batch of plates, the water having been standing in the main the development was normal. When it is possible to procure ice a little may be used to keep the solutions at a normal level. Failing this, a little bromide solution may be added to the developer, and the developer also used of a less strength than in cooler weather. Any tendency to over-expose must be avoided, and this is best done by slightly reducing the aperture of the lens, as when working one is apt to forget that allowance has to be made for the stronger light we are now enjoying. In many cases a slower plate may be employed with advantage, but it must be remembered that such plates are rather quicker in attaining density, so that over-development must be guarded against.

Corrosion of Lenses. If lens users would acquire a little elementary knowledge concerning the nature and properties of glass, their instruments would stand a much better chance of keeping in good condition than they do at present. It should be known that what we call "optical" glass is made in a great variety of qualities, each of which is capable of taking its place in one or other of the many kinds of lenses. Some are as hard and impermeable as the glass we use for windows and tableware, while others are soft enough to be easily scratched or even dented, while injudicious polishing will quickly dim the exquisite surface upon the perfection of which so much depends. This is especially the case in some of the earlier anastigmats in which very soft and easily corroded glasses were used because others were not available. It is perhaps news to many people to learn that some glasses are so susceptible to damp that a single drop of water left upon the surface for a few hours will leave an ineradicable mark, while the presence of a film of condensed moisture will give rise to a general corrosion, which in mild cases shows in prismatic colours like those of a soap-bubble, and in severe ones as a yellow stain

accompanied by a distinct depolishing of the surface. Unfortunately, there is no cure for this evil, for even the maker of the lens cannot repolish it to the same accuracy of figure that it originally possessed. Forewarned is forearmed, and knowing what is likely to occur the prudent man does not allow his lenses to stand about exposed to the atmosphere, but keeps them in tightly-closed cases when they are not actually in use. Failing a case, which also protects the brass work, a well-fitting cap at the back as well as the front is an excellent protection.

* * *

Exposure in Enlarging. An American writer, the Rev. C. R. Lowe, has given particulars of a method for estimating exposures in daylight enlarging which has some features of novelty about it. Summarised, it consists of making a contact print from the actual negative to be enlarged from, using daylight for the purpose, and, of course, employing the same kind of paper as will be used for the large print. The apparatus is of the usual daylight type; that is to say, a window is blacked up leaving only an opening rather smaller than the camera back. Against this the camera is fixed, and the image projected upon an easel in the usual way. The problem is now how to establish a definite ratio between the exposure for the enlargement and that of the contact print. To do this a correctly exposed enlargement is made by the usual trial and error or strip methods, and the time taken with a certain stop (in the author's practice this is always $f/11$) is noted. For example, this may be 15 secs. with an enlargement of $1\frac{1}{2}$ times. A second opening of about 10×8 , with an easily moved shutter, is provided in the window board, and the contact print made at such a distance from this that the correct exposure is also 15 secs. It then follows that any other negative exposed in the same position and the same distance from the opening will yield a good print with the same exposure as will be required in the enlarger. Other magnifications than $1\frac{1}{2}$ diameters will need the exposure to be increased in a definite proportion. A convenient table for calculating this will be found on page 407 of the current "B.J. Almanac."

* * *

Cloud Negatives. It is not a good practice to start out with the intention of making cloud exposure exclusively, as this tends to securing a number of negatives of very much the same character. It is better when out on other work to devote a plate or two to any particularly good cloud effect, and to make a note which can be transferred to the bottom edge of the plate as to the point of the compass at which the camera was pointing and the time of day when the exposure was made. Although it is possible occasionally to obtain good results on an ordinary plate without a yellow screen, it is much easier to do so with an orthochromatic plate and a proper filter. There is really no reason why the landscape photographer should ever expose an ordinary plate and many reasons why he should use colour-sensitive ones. It is a mistake to use too dark a colour screen for sky work, the K2 strength being quite sufficient to give the proper contrast. If a deeper colour be used the blue portions will come out practically black and the sky will look too heavy for the view. In our idea most sky negatives are too thin, as this adds considerably to the difficulty in printing them to the proper depth to suit the subject, particularly when enlarging or printing upon bromide paper. This often leads to an unnatural appearance in the finished print and causes some people to contend that a perfect result can only be obtained when the clouds are secured upon the same plate as the view. The real reason for this is that in this case the clouds have received full development, which can also be given with a properly screened plate. We may perhaps

be allowed to remind those who are not experienced in this class of photography that it is always desirable to include a narrow strip of landscape below the clouds, so that the negative may not be used upside down. This has the additional advantage of preventing the camera being pointed to the zenith and the resulting clouds printed in near the horizon, a fault which has often been committed.

SOME ITEMS IN THE USE OF THE VEST-POCKET CAMERA.

As we have mentioned now and again in these columns the vest-pocket camera, now so popular with the amateur worker, is an instrument not to be neglected by the professional photographer. While it can never supplant cameras of much larger size which are employed on stands, it has supplementary uses for which its small size and optical performance particularly qualify it. There are many occasions when photographs turn out to be required in addition to those which the photographer has equipped himself to take. A vest-pocket camera with an ample supply of plates or roll-film occupies an insignificant space in the larger kit, yet is able to turn out work which can be quite satisfactory for commercial purposes. In other conditions the possession of the small camera may encourage the photographer to take negatives speculatively: the time and cost thereby involved are small, and will often be repaid by the orders secured. From these considerations some thought may well be given to the choice of a camera of this size and to the best methods of using it.

In regard to the camera the first essential is that it should be of the finest mechanical construction and fitted with a lens as good as can be had. In an instrument of this small size, where a difference of a minute fraction of an inch may spoil the definition, it is bad policy to buy a camera which does not provide a thoroughly rigid and square position of the lens in respect to the plate or one which is liable to develop defects with use. There is fortunately considerable choice. The purchaser may choose between cameras of the folding focal-plane pattern, in which the lens front is held forward by a system of rigid struts, and those of the folding baseboard type. In both classes instruments are to be found which are beyond criticism in their mechanical construction. As a rule-makers fit a lens of $f/4.5$ aperture, and in many circumstances there is an advantage in this maximum speed. Moreover, $f/4.5$ is the fashion, and a camera of this aperture is much more saleable, if one wants to dispose of it, than one of $f/5.6$ or $f/6$. Nevertheless, for such commercial photography as may be undertaken with a vest-pocket camera, there is little to be gained in having a larger aperture than $f/6$. The negatives are taken with a view to enlargement to whole-plate size, and for this purpose the greater depth and more acute definition at $f/6$ are recommendations for this aperture. As regards focal length we are largely in the hands of the manufacturers, but it may be said, even if a camera can be found, there is no object in having a lens of focus shorter than three inches. Rise of front, if it can be had, is certainly an advantage at times, but most cameras of this size are without it. Thus, where the camera has to be tilted in order to include parts of a subject which contain vertical lines, recourse must be had to correction when enlarging by the customary method of tilting both the negative and the bromide paper towards each other.

For various reasons roll-film is a sensitive material for the vest-pocket camera to be recommended. The camera is ready for use at a moment's notice, development of the small negatives is more readily done and without touching

them than when plates are used, and it is the experience of many that minute mechanical defects of manufacture are of less occurrence in these small roll-films than in plates of the same size. It may be urged that the use of roll-film prohibits focussing on the ground glass, but in any case the image on a vest-pocket camera is really too small to be seen satisfactorily, and it is quite safe to rely for the arrangement and focussing of the image upon a tested direct vision finder and focussing scale.

The great merit of the vest-pocket camera for many descriptions of commercial photography, and particularly of indoor subjects, is the combination of rapidity and depth of focus which results from the use of such a short-focus lens. As the reader can readily reckon for himself a 3-in. lens of $f/4.5$ corresponds, as regards depth of focus, with a 10-in. lens at $f/16$, whilst the former has the advantage over the latter as regards shortness of exposure of more than twelve times. In other words, for work such as the indoor photography of machines and similar subjects, the user of a vest-pocket camera is able to make a whole series of exposures during the time that one plate is being exposed with his half-plate or whole-plate outfit. A light tripod is almost necessary for this work, although some commercial photographers that we have known carry a little fitting on the head of the ordinary tripod consisting of a grip for a vest-pocket camera. In photographing, even on such a small scale as 60 x 45 mm., the mistake must not be made of getting too close to the subject. It is by so doing that the results with the small instrument are likely to be condemned as unsatisfactory. The drawing or perspective of a solid object is conditioned by the distance of the lens from it. While its near viewpoint is the least satisfactory element in the use of the

vest-pocket camera a rendering of the subject, which would be defective from this cause, will be better as the camera is used farther away. At the same time, with the correct adjustment of the focussing scale, depth of definition will be correspondingly greater and the enlarged print show to correspondingly better advantage as regards detail.

A general all-over sharpness is the greatest merit a vest-pocket camera negative can possess, and if care is taken when focussing there ought to be no difficulty in making whole-plate enlargements perfectly sharp from corner to corner from each negative, but the definition in the first place must be needle sharp. Perhaps the most formidable difficulty in the way of making large prints from the tiny negatives is the grain of the latter. Much may be done to avoid this grain by the use of plates of somewhat slower speed, and by the employment of a developing formula which results in an image of finer grain. The Wellington borax metol-hydroquinone developer is a most satisfactory formula for this purpose, and it is hardly necessary to point out that, as in the treatment of any plate, unforced development is a condition for the production of a silver image of the finest grain.

As regards enlarging, it need only be said that where enlarged prints over whole-plate size are required a certain amount of working-up may be necessary. Such work on the small negatives is very inadvisable; the better plan, apart from simple spotting, is to make an enlargement upon smooth bromide paper, and work upon that. A copy negative is then made from the worked-up enlargement upon a plate of the same size.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).
The Postcard Studio (March 14).
The Printing-Room (March 21).
About the Reception Room (March 28).
Home Portraiture (April 4).

Portable Studios (April 11).
Copying (April 18).
Handling the Studio Camera (April 25).
More About Lenses (May 2).
Enlargements (May 9).
Advertising the Studio (May 16).
Mounts and Mounting (May 23).
Business Methods (May 30).
Photographing Children (June 6).
Portraits of Elderly People (June 13).
Something about Lenses (June 20).
Hand Cameras for Professionals (June 27).
The Dark-Room and Its Fittings (July 4).

PLATES AND THEIR WORK

My experience of photographic plates goes back to the time when the only kind of dry plate upon the market was of the collodion variety, although experimenters were busy with gelatine, which it was hoped might ultimately be made as rapid in action as wet collodion. Even when a satisfactory plate was made it had a hard fight to get into the professional portrait studio, mainly because the handling during development and fixing was so widely different from what we had been accustomed to. Besides this the plates themselves were by no means uniform in speed and quality, and the unhappy operator never knew whether to blame himself or the plate-maker for a failure. I need hardly say that he usually did the latter, as some do

even now, although I think that nowadays one may safely say that there are no bad plates; some kinds may suit a particular worker's methods better than others, but all are capable of giving good results if handled in the right way.

The quality of a negative does not seem to be so much regarded as it was in earlier days, when albumenised paper was the only printing medium, and a decent negative was necessary to get any brilliancy of image and beauty of tone. Now any old sort of image is passed, and it is left to the printer to find, out of the hundred and one sorts on the market, a paper which will yield a print which the customer will not reject. This is mainly due to carelessness in exposure and development, but

also in some cases to the choice of a plate which is unfitted to the particular job.

So far as my experience goes there is no single grade of plate which will give the best results with all classes of work, yet we find plenty of photographers who do not realise this, and do portraits, interiors, and copies on identically the same emulsion. That the results are as good as they frequently are speaks volumes for the operator's skill; but they would be much better if a second, or even a third, variety were kept ready for use. The fact that all our best plate-makers issue a number of grades of plate which differ not only in speed but in the quality of the image ought to make it clear that the "universal" plate does not exist, for if it could be made it is pretty certain that the plate-makers would make that grade only.

Failing this, we must select from the various plates at our command those most suitable to the work to be undertaken. In my opinion (others may differ) the slower the plate used, the more satisfactory the result, for the reason that, as a rule, slow plates allow far more latitude in exposure, and therefore better printing negatives can be obtained. I do not for a moment wish to deprecate the value of even the most rapid plates for their proper work, only their use on such subjects for which speed is not necessary, and especially where such contrasts exist that certain portions must be over-exposed in order to secure detail in others. Even in portraiture, for which ultra-rapid plates are usually chosen, it is not always wise to use them if really fine quality is wanted. It is true that the rapid plates give full detail, and apparently satisfactory quality, but if a little more exposure could be given a slower plate would give a better modelled image with finer printing quality. This is especially the case where there are white or very light draperies, which lose all their sparkle if the other parts of the picture are adequately exposed. Therefore, it is wise to be content with a plate not faster than 200 to 250 for the majority of portrait negatives, and to reserve those of higher speeds for children, animals, and for ordinary sitters in a bad light. For outside work they should only be used for fast shutter exposures. It has been stated by some hand-camera experts that the speed number of a plate, even if correct, is not of itself a safe guide to its image-producing capacity, for a rather slower plate may under trying circumstances give an image of some printing value, while the rapid plate gives a negative showing slightly more detail, but which cannot be forced up to printing strength. Another defect in most very rapid plates is the coarseness of the grain, which renders them quite unfit for any considerable degree of enlargement.

For general outdoor work my limit of speed is 250 H and D, and this I should employ only for groups which required a small aperture, and for shutter exposures, on horses, cattle, and the like. Whenever circumstances permit I prefer the "ordinary" speed, which is about 100 H. and D. With this it is possible to expose for four or five times the correct time and still get a good negative by straightforward development. For interiors or other subjects showing strong contrasts, such as

white buildings among dark trees, the slow plate scores again, for it will give detail in both light and shade, while the rapid one would have given a flat result in the lights by the time the shadows had got enough. I am, of course, assuming that development is properly carried out, because very rapid plates are often accused of giving thin images, the fact being that such plates require a much longer time to attain full density than slower ones do.

For copying it is usual to employ slow plates, and the ordinary grade usually gives a satisfactory result with all except line subjects, such as pen-and-ink drawings, letters, printed matter, and the like; to get the best results with these and with any monochromes which are flat or lacking in contrast, process plates are a necessity. I had recently to copy a very badly faded silver print, and after various trials with ortho-plates, with and without screen, decided to try a "process" with which I obtained a very fine negative; the paper was quite yellow and the image faint brown, yet in spite of theory the result was most satisfactory.

Ortho plates are not as generally used as they should be. Used without a colour screen they will do all that an ordinary plate will do, and with a screen they will give results otherwise impossible. They should be used for such work as flowers, trimmed hats, and fashion work generally, and, of course, for all coloured prints, water-colours, and light oil paintings. Type-written letters, which are usually in violet ink, need a somewhat deep yellow screen, such as the K. 3, to give sufficient contrast. Panchromatic plates may be considered as super-ortho plates, as they are practically sensitive to all colours. They are indispensable for such subjects as furniture, dark oil paintings, fabrics with patterns in strong colour, and for very difficult portraits. The most freckled sitter will come out with a perfect complexion on a panchromatic plate with a K. 2 screen, and light-blue eyes are rendered in their true values.

To obtain the best results on any subject with strong contrasts backed plates should be used, for it is not fair to the emulsion to allow the high-lights to be choked up by halation. It has been stated that backing reduces the speed of a plate, but this I can positively assert is not the truth. A brighter image is certainly obtained, and this may have given rise to the impression, but so far as detail in the shadows is concerned I have found that there is no advantage in using an unbacked plate, while the rendering of the high-light detail is always greatly superior, this being considered quite apart from the absence of blurring or halation as is generally understood.

As a concluding hint I would say, choose a good brand of plate, master its working thoroughly, and do not forsake it without good reason. Plates have their little ways, and so have operators, and the great point is to see that these fit in together. Some plates develop more quickly than others; some work better with a warm developer which would fog another brand. These things must be found out and carefully noted, and many failures and half-failures will be avoided.

PRACTICUS.

THE CONVENTION OF THE AMERICAN PHOTO-ENGRAVERS' ASSOCIATION.—For their annual convention on June 19, 20, and 21, at Buffalo, New York, the executive certainly had an excellent programme scheduled, for, in addition to the usual routine business of these meetings they selected all the prominent men in the industry to speak on topics with which they are specially familiar, and which are of importance to the trade at the present time. The subjects were divided into four main heads—"Production," "Advertising and Selling," "Executive and Administration," and "Labour Policy." Under "Production" were papers on "How to Reduce Costs of Production and Selling Price," by five authors (one of whom, we observe, is an old-time contributor, Mr. A. J. Newton), also several papers on "Standardising Shop Methods and Practice," and "Standardising Three-Colour Inks." It is a relief

to see that technical problems receive some attention as against the perennial question of price, though this, of course, was not neglected, and papers were down for reading on "Differential Discounts and Prices," "Fair and Unfair Competition in Selling and Buying," "Proper Charges for Overtime," and five aspects of the problem of "The Middleman." A sign that the Labour problem is as acute in the United States as it is here is the fact that the president of the Trade Union was invited to speak on the "Aims and Objects of Organised Labour," that the secretary of the Employers' Association spoke on "Our Relations With Labour," that two employers spoke on "Profit-Sharing and Bonus Systems," and five leading employers spoke on "The Forty-Four Hour Week," which faces the trade in America next year. We hope to give some of the conclusions arrived at by this Convention as soon as they are to hand.

HOW TO PREPARE PHOTOGRAPHIC SOLUTIONS.

[In the following paper, previous instalments of which have already appeared, Mr. J. I. Crabtree of the Eastman Research Laboratory, deals in a most explicit and comprehensive way with the practical methods of making up photographic solutions in bulk and with the chemical proportions which require to be taken in accordance with the properties of the substances which are being handled. Although contributed for the information of cinematograph photographers to the "Motion Picture News" there is scarcely a single paragraph of it which does not apply to the customary operations of any photographer working upon a reasonably large scale; and there is, we think, no photographer so fully expert in the compounding of such solutions as developers, fixing baths, etc., who will not get some practical hints from it.—Eds. "B.J."]

(Continued from page 382.)

How to Mix Fixing Solutions.

Fixing baths may be divided into the following classes:

1. Plain hypo solutions.
2. Acid hypo solutions consisting of hypo, with the addition of sodium bisulphite, potassium metabisulphite, or sodium sulphite with acid.
3. Acid hardening hypo solutions.

1. No difficulty is usually experienced when mixing a plain hypo solution. When mixing a quantity of solution in a tank the filter-bag method should be used and the hypo dissolved in warm water, because the temperature drops considerably while the hypo is dissolving. If a scum forms on the surface of the solution on standing this should be removed by drawing the edge of a towel across the surface.

If a wooden cover is used for the tank, fungi often develop in a hypo solution and produce acid substances which tend to turn the solution milky. In such a case the tank should be thoroughly cleaned, and the cover faced with sheet lead.

A plain fixing bath, however, is seldom used, because it gradually becomes alkaline from an accumulation of alkali carried over by prints and plates from the developer, and this tends to soften the gelatine while the image continues to develop in the fixing bath, so that if two prints stick together more development takes place at the point of contact, causing uneven development. If the bath is acid, the acid kills or neutralises the alkali in the developer carried over, thus preventing unevenness.

2. In order to be able to mix an acid fixing bath intelligently it is necessary to understand a little about the chemistry of the acid-fixing bath.

Hypo can be made by boiling together sodium sulphite and flowers of sulphur until no more sulphur is dissolved. If acid is added to a hypo solution sulphur is again liberated, forming a milky solution known as milk of sulphur. If sodium sulphite is present, however, any sulphur which tends to come out of solution combines with the sulphite to form more hypo, and the solution therefore remains clear.

This sulphur cannot be redissolved by adding sodium sulphite to the milky solution except by boiling, while on standing it is apt to settle on prints or plates as a scum. All acid-fixing baths therefore contain either sodium bisulphite, potassium metabisulphite, or a mixture of sodium sulphite and some acid, and the following directions for mixing should be followed:

(a) Do not add the bisulphite or acid sulphite solutions to the warm hypo solution. The solutions should be perfectly cold when mixed, or the hypo will turn milky.

Experience has shown that potassium metabisulphite has less tendency to produce milkiness than sodium bisulphite, though for practical purposes the difference is almost negligible.

Of the common acids, sulphuric, hydrochloric, acetic, citric, etc., acetic, citric, and tartaric acids have less tendency to produce milkiness for a given degree of acidity than sulphuric, which fact would be expected from theoretical considerations.

(b) On keeping, an acid hypo solution gradually becomes milky, so that a stock solution of the sodium bisulphite, etc., should be kept and added to the plain hypo stock solution as required. For general purposes 50 c.c.s. of a 50 per cent. sodium

bisulphate solution are added to 1,000 c.c.s. of a 35 per cent. hypo solution. If any considerable excess over this amount is added, the hypo rapidly turns milky owing to the liberation of sulphur, especially in warm weather.

3. Acid hardening baths are prepared by adding to hypo an acid hardening solution which contains the following ingredients:

(a) An acid such as acetic, citric, tartaric, lactic, sulphuric, etc., which stops development.

(b) A hardening agent such as alum, chrome alum, or formalin.

(c) A preservative such as sodium sulphite or sodium bisulphite.

The latter acts as a preservative in two ways. It prevents the formation of sulphur by the action of the acid on the hypo, while it also prevents the developer carried over into the fixing bath from oxidising and turning brown.

How to Mix the Acid Hardener.

Prepare the acid hardening solution as to separate stock solution, and add this to the hypo solution as required.

The order of mixing is important, as follows:

(a) When mixing in one vessel, first dissolve the alum in warm water, then add the acid and add the sulphite immediately, otherwise if the acid alum solution is allowed to stand the alum will crystallise out again. It is sometimes recommended to reverse the process, namely, dissolve the sulphite first, add the acid, and then the alum, but unless the alum is finely powdered this does not readily dissolve unless the solution is warm, in which case sulphur dioxide gas is given off from the acid sulphite solution.

(b) The best method is to dissolve the alum and sulphite in separate solutions, cool, add the acid to the sulphite, and then add the alum solution.

If the order of mixing is reversed, and the alum first added to the sulphite, a white sludge of aluminium sulphite is formed which dissolves with difficulty when the acid is added. Therefore if after mixing the hardener is milky and a sludge settles out, this is due to a relative insufficiency of acid, that is the acid used was either not up to strength, or too much alum or sulphite was added.

With all other hardening baths the order of mixing is the same.

Fixing Bath Troubles.

1. *Milkiness of the Fixing Bath.*—Sometimes a fixing bath turns milky immediately on adding the hardener, and sometimes after being in use for some time. The milkiness may be of two kinds:

A. If the precipitates settles very slowly on standing, the milkiness is due to sulphur, and may be due to the following causes:

(a) Too much acid in the hardener.

(b) Too little sulphite or the use of impure sulphite, in which case there is not sufficient present to protect the hypo from the acid.

(c) High temperature. The hardener should only be added to the hypo solution when at room temperature. If the temperature of the acid fixing bath is over 85° F., it will not

remain clear longer than a few days even when mixed correctly. The only remedy is to throw the bath away, and mix fresh solution as required.

B. If the milkiness disappears on standing for a few hours, and a gelatinous sludge of aluminium sulphite settles out, this is caused by:

(a) Too little acid in the hardener. For example, supposing a formula calls for pure glacial acetic acid, and 28 per cent. acid is used by mistake, then we have added less than one-third the required amount.

(b) Too little hardener in the fixing bath. When fixing prints, a relatively large proportion of the developer is carried over to the fixing-bath, which soon neutralises the acid, and therefore permits of the formation of aluminium sulphite. In the same way a fixing-bath with the correct proportion of hardener when exhausted, still contains alum and sulphite but no acid, and these combine to form a sludge of aluminium sulphite.

It is extremely important therefore to use only acid of known strength, because trouble is caused if we use either more or less acid than is called for in the formula.

2. *The Bath Does Not Harden.*—A frequent cause of insufficient hardening is the use of inferior alum which does not contain the correct proportion of aluminium sulphate. An exhausted bath which is alkaline will also harden very slowly, since alum hardens best only in acid solution.

Substitution of Chemicals.

Occasion often arises when the photographer is out of stock to some particular chemical, and he is tempted to substitute the chemical by another. In this chapter it will be shown how far substitution is possible in the case of developing and fixing baths, though the remarks will usually apply also to solutions in general.

In view of the present scarcity of potassium salts and their greater expense as compared with sodium salts, the question arises as to what extent they can be replaced by salts of sodium or ammonium.

As a general rule, for photographic purposes, a potassium salt can be replaced by a sodium salt weight for weight, the error caused by the difference in molecular weight of the two salts being usually negligible. There are many exceptions, however, where there is a difference in the physical properties of the two salts for example, potassium carbonate and sodium bichromate are deliquescent, while sodium carbonate and potassium bichromate are not.

Substitution in Developing Formulae.

1. *The Developing Agent.*—As a general rule it is not possible to replace one developing agent by another and obtain a developer with identical properties, because each developing agent has its own characteristics as regards rate of development, for colour of image produced, etc. In some cases, however, a close approximation can be made, for example by substituting Elon by Kodelon (or paramidophenol) providing the developer is sufficiently dilute to permit of sufficient paramidophenol being dissolved. This applies either to an all Elon or an Elon-hydroquinone formula.

If in an Elon-hydroquinone (or E-H) formula paramidophenol is substituted for the Elon and the activity of the developer is increased by the addition of alkali, the effect of the alkali is proportionately greater on the hydroquinone than on the paramidophenol so that a rapid hard-working developer is obtained. To avoid this, proportionally more paramidophenol is required than if Elon is used.

2. *The Preservative.*—It is now customary to substitute sodium bisulphite for potassium metabisulphite weight by weight, though in a plain fixing bath-sodium bisulphite has a slightly greater tendency to produce sulphurisation than the potassium salt.

The question is often asked as to the difference in action be-

tween sodium sulphite and sodium bisulphite. Sodium bisulphite may be considered as a compound of sodium sulphite and sulphurous acid, and therefore reacts acid, while sodium sulphite is alkaline, so that in the case of a two-solution pyro formula where the pyro A solution is preserved with oxalic acid or sodium bisulphite, an equal weight of sodium sulphite would not preserve so well since pyro oxidizes much more readily in alkaline than in acid solution.

In the case of a one-solution developer containing, say, sodium sulphite, sodium bisulphite and sodium carbonate, the bisulphite is converted to sulphite by the sodium carbonate, according to the following equation:—Sodium bisulphite + sodium carbonate = sodium sulphite + sodium bicarbonate; so that a corresponding amount of sodium sulphite might just as well have been added in the first place. Sodium bisulphite also neutralises or destroys an equivalent amount of sodium carbonate, thus reducing the proportion of alkali, and therefore exerts an apparent restraining action, while the developer apparently keeps longer because some of the carbonate has been destroyed. The relative amounts of the different salts which produce the same preserving action is given in the following table:

Sodium sulphite	1.0 parts
Sodium bisulphite	8.3 parts
Potassium metabisulphite	0.88 parts

For a two-solution developer therefore use sodium bisulphite, but in a case of a single solution developer containing alkali use sodium sulphite, because in this case no advantage is gained by using a mixture of sulphite and bisulphite.

3. *The Alkali.*—The common alkalis are the carbonates and hydroxides of sodium, potassium, or ammonium. Substances like acetone, tribasic sodium phosphate, borax, and amines are occasionally used, but will not be considered here.

When sodium carbonate is dissolved in water a small portion of it reacts with the water forming caustic soda and sodium bicarbonate; this is called hydrolysis, though only a small portion of the carbonate is hydrolysed at any moment. As the caustic soda formed is used up in development, more carbonate hydrolyses so that we can consider that carbonate acts as a reservoir of caustic alkali. If in the first place a solution of caustic soda was used of the same alkalinity as the carbonate this would soon be used up. The use of carbonate therefore enables us to use a small concentration of alkali, and yet keep it constant during development.

It is rarely possible therefore to replace caustic alkalis by carbonated alkalis such as sodium or potassium carbonate.

Potassium carbonate is slightly more active than sodium carbonate in solution because it hydrolyses to a greater extent. For developing motion picture film on a reel when the developer may splash on the floor, potassium carbonate cannot be substituted by sodium carbonate since, because of the deliquescent nature of potassium carbonate, the splashes of solution remain moist thus preventing the formation of carbonate dust in the air.

Caustic soda and caustic potash may be replaced weight for weight in most formulae.

Ammonia and ammonium carbonate are seldom used in developers on account of the odour, and the fact that they tend to cause dichroic fog.

Desiccated and Crystal Sodas.

Sodium carbonate and sodium sulphite are often supplied in two forms: Crystals and the desiccated or dry variety, which is sometimes called anhydrous, because it does not contain water of crystallisation.

Desiccated sodas possess the advantage that they occupy less than half the bulk of the crystals, while desiccated sodium sulphite is much less liable to oxidation by the air than the crystalline variety.

The sodas should be substituted as follows:

One part by weight of sodium carbonate (desiccated) for three parts by weight of the crystals.

One part by weight of sodium sulphite (desiccated) for two parts by weight of the crystals.

4.—The Restrainer.

Potassium bromide may be substituted by an equal weight of sodium bromide. Ammonium bromide should not be used in a developer because the alkali liberates ammonia gas, and this tends to produce dichroic fog as above.

Substitution in the Fixing Bath.

Sulphites and Bisulphites.—The same remarks apply as to preservatives in the developer.

Alums.—An alum is a compound or double salt of aluminum sulphate or chromium sulphate with either sodium, potassium or ammonium sulphate. The hardening action is only produced by the aluminium or chromium sulphate, so that equivalent weights of aluminium sulphate and of sodium, potassium, or ammonium alum should exert the same hardening action.

As a result of a series of practical tests by the author, the following conclusions have been drawn:

(a) Equivalent amounts of potash alum and aluminum sulphate exert the same hardening action, two parts by weight of aluminum sulphate, being equivalent to three parts by weight of potash alum. Commercially pure aluminum sulphate is satisfactory if this does not contain an excess of iron, though if the sample is acid the solution should be neutralised with ammonia. When mixing the usual liquid hardener formula with commercial aluminum sulphate, a slight milky suspension is formed which should be allowed to settle and filtered off.

(b) There is no appreciable difference between sodium, potassium and ammonium alum in their hardening action when substituted weight for weight in the usual formulæ. In practice, if any difference in hardening action occurs, this is due to the use of impure alums, in which case, providing the impurities are harmless, an increased amount of the alum should

be used so that its content of aluminum sulphate is the same as that in the potash alum called for by the particular formula.

When using ammonium alum, if the fixing bath becomes alkaline by virtue of a neutralisation of the acid by the developer carried over, ammonia will be liberated resulting in the production of dichroic fog and stain. No trouble will be experienced, however, if care is taken to keep the bath acid.

Pure chrome alum may also be substituted for potash alum, as above, though it has a slightly greater tendency to precipitate sulphur than potash alum. It has the advantage, however, that it does not form a basic sulphite as rapidly as potash alum, so that a chrome alum fixing bath remains clear even when appreciably alkaline.

Acids.—The most commonly used acids are acetic, citric, tartaric, and sometimes lactic acid. Strong acids like sulphuric are seldom used because of the great tendency to liberate sulphur. Weaker acids like the above bear the same relation to a strong acid as a carbonated alkali to a caustic alkali, that is they act as a reservoir of acid, so that only a small portion of the acid is available for reaction in solution at any one time.

Acetic acid is usually supplied in two strengths, glacial (98 per cent.) and 28 per cent. acid, so that one volume of glacial acid is equivalent to three and a-half volumes of 28 per cent. acid.

Citric and tartaric may be substituted weight for weight and when used in place of acetic, substitute in the ratio of one gram of citric for every 3 ccs. of 28 per cent. acetic acid.

However these acids are not quite so satisfactory as acetic because for a given degree of acidity as measured by the amount of alkaline developer which can be added to the fixing bath before the bath becomes neutral, citric and tartaric acids have a greater tendency to precipitate sulphur from the hypo than acetic acid.

J. I. CRABTREE.

(To be continued.)

LOCAL VIEWS AS POSTCARDS.

WHEN local view postcards were first introduced, I was among the first to prophesy that it was not likely to be a passing fancy or a craze for the moment; it seemed to me then, and it seems to me now, that the trade, once introduced, had come to stay, and although from three or four causes the trade has fallen off of late, there seems to me no doubt whatever that directly these causes are removed there will not only be a thorough revival of business in this line, but a steadily growing increase in the output. The causes which have led to the decreased sale not only of local view postcards but of pictorial postcards generally, have been, first, the war and the general upheaval of business all round consequent upon the same. Secondly, the great and ever-growing increase in the cost of all materials and the shortage of supplies of glass, paper, and chemicals, which necessitated an increase in the price of the finished cards, and on the top of the dearer card came the extra postage. Where a card could be bought for a penny and posted to any address in the United Kingdom for a halfpenny—a total cost of three halfpence—it now costs threepence or sometimes twopence halfpenny, whereas a letter of several sheets and weighing as much as four ounces could and can be posted for three halfpence. And now, six months after the signing of the Armistice, the postage rate on a postcard still remains at a penny. This high rate has done more harm to the postcard trade than has arisen or is likely to arise from any other cause or from all other existing causes combined. Surely it is time that the Government saw fit to revert to the old halfpenny postage on postcards; the extra halfpenny on a letter we do not grumble at, although it is an increase of 50 per cent., whereas the postcard rate is increased 100 per cent. If all the producers and publishers were to combine and, together with the retailers, approach the Government on the matter, there

seems a reasonable hope that this 100 per cent. tax may be removed. It should be mentioned that if the superscription "Postcard" be struck out and replaced by "Printed Papers," and the message limited to five words of conventional character, a pictorial card may be sent at the halfpenny rate. Another cause of decreased demand in postcards was D.O.R.A.'s enactment that no photograph should be sent to any neutral country. This is, of course, now obsolete, but whole armies of Belgians and others who were in this country have now returned without having purchased any of the many thousands of photographic postcards which they would otherwise have done. A further cause of bad sales has been another of "Dora's" rulings which prohibited outdoor photography, and so stopped the taking of fresh views. Any dealer in postcards will tell you that the infusion of a few new subjects with the old periodically gives a considerable impetus to the sales, besides which no self-respecting stationer likes to keep the same old views in his window month after month, season after season, and year after year; even one or two new ones mixed in occasionally make a change and draw attention, whereas the public seeing nothing fresh pass on without a second glance.

In all probability we shall never get back to the penny (photographically produced) postcard; but if the price is in the future to remain at twopence, or even three halfpence, the sale will still be a good one if we endeavour to improve upon the pre-war penny article. Undoubtedly the present postcard can be improved upon in more ways than one. The first improvement that suggests itself is that the card itself should be considerably heavier or thicker than that in general use at present, and which is very often but little stouter than ordinary drawing paper. These very thin cards do not make a good show in the window or in the stand, as they curl inwards and

look, to say the least of it, untidy. I have more than once heard dealers say they would rather pay a slightly higher price for a thicker card, and they would undoubtedly appeal to the public. Then why is it that nine out of every ten publishers print the cards flat, or, in other words, full out, which gives the prints, unless they are guillotined, an untidy look. And it should be borne in mind that a guillotined print is almost invariably under the regulation size allowed by our grandmotherly postal officials, and this, when discovered by the aforesaid G.P.O.s, results in a surcharge of another halfpenny on each card so discovered, and payable by the recipient. When a postcard is printed right out to the edges, these edges always present a rough and unfinished appearance, which does not occur when printed with a narrow white border, and it is somewhat astonishing what a difference in the general appearance of the card results from the varying width of the border; where bordered prints are issued the usual width is one-eighth of an inch, while in some cases it more nearly approximates to the quarter. Now, just take one of these cards and retrim so that the white border is only one-sixteenth of an inch, and note the astonishing improvement in the effect. Surely it is very little more trouble to print with that width of border than with the greater, to which may be added the further advantage accruing from the increased size of the picture itself, often enabling the top of a church steeple, or other high building, to be included without unnecessarily cutting off the foreground. Some care is needed in placing the bordered negative in the printing machine so as to ensure an *even* sixteenth of an inch *all round*, as nothing looks worse than a wide border on one or two sides and a narrow one on the others.

Another improvement I would advocate is in the matter of skies. Here perhaps the improvement may add a trifle to the cost of production, but a trifle which will be amply repaid by the improvement in the resulting prints, and consequently an improvement in their popularity. The terribly crude white skies which almost everywhere obtain must be an eyesore to the person with any art education, and when it is remembered that a dead-white is not a correct rendering of even a clear and cloudless blue sky, it will be seen that the photographer who wishes to improve his work, and incidentally his output, has here scope for a very material improvement. A grey sky (printed through) is almost as bad as a dead-white, and the alternative presents itself of introducing artificial clouds, or, at any rate, clouds by artificial means. But how is this to be done on a cheap bromide postcard? queries the printer. Well, I said it would cost you more, and I would suggest the following as the best *modus operandi*:—The negative should always be taken of a larger size than a postcard. A half-plate will do, but a whole-plate is much better, and from this a perfect print should be made and *suitable* clouds printed in. From this print a second negative

should be made, which will, of course, include the clouds, and note here that all negatives from which hundreds or thousands of prints may be required should be varnished. The system of rubbing down the opaque sky of the original negative with Bluebell or Globe polish to form clouds might answer in some cases, but it would need a very skilled hand and a very artistic eye to produce a result excelling or even equalling the method I have suggested. Where the original negative is thin and the sky grey, some workers proceed to cover the glass side with papier mineral and work the clouds in on this with a stump and blacklead powder. This method has two objections; first, it does not yield results equal to a cloud negative; and, secondly, any experienced eye can at once tell the way the effect (such as it is) has been produced. At the first blush it may seem that the extra cost of a larger negative and copying again is too much; but it must be borne in mind that the extra cost is very small, and the extra time taken in the production of a plate from which, not dozens, but dozens of grosses are to be produced will be well repaid in a very short space of time.

Some publishers there are who opine that a series of a dozen negatives is ample for any moderate-sized town. It is, nevertheless, a fact that with a series of twenty-four or thirty-six the sales all round increase in proportion, and the cost of producing three dozen negatives of one locality, instead of one dozen each of three different ones, is materially reduced. Naturally, there are some towns or villages where not even a dozen selling subjects can be found, and others where the number may exceed a hundred. The operator must perforce use his own discretion, and will no doubt receive valuable assistance in the selection of subjects from some of the prospective customers. A word to the operator: When viewing, do not, for mercy's sake, pop down your camera and photograph your subjects from the first point of view. Rather spend a few minutes, or even half an hour, in inspecting it from every possible point of view, and *then* photograph it from the very best. If the light is wrong at the time, go on to your next subject, and come back to the first when the light is right. Never mind if it is six in the morning or seven at night: the final result will justify the extra trouble and recompense any personal discomfort. When photographing a water subject with reflections, care should be taken to avoid getting the reflection as sharp and clearly defined as the subject reflected. There are too many view photographs about already in which the observer is puzzled as to which is the right way up; remember that the swing back is just as useful to throw one part of the picture slightly *out* of focus as it is to bring the whole of it *in*. In all street views some sign of life should be introduced—trams, omnibuses, market carts, tradesmen's vehicles, each of them in turn may suit the subject, and pedestrians and bicyclists are never out of place.

C. BRANGWIN BARNES.

THE PHOTOGRAPHIC CORRECTION OF NEGATIVES TAKEN OBLIQUELY.

[For the purposes of the French Army Aviation Service, in which he was engaged during the greater part of the war, M. L. P. Clerc has investigated with great thoroughness the mathematical conditions involved in transforming a photograph taken from an inclined aerial camera into one corresponding with that obtained from the same view-point, but with the lens axis vertical. His study has led him to the design of a purely automatic camera carrying out this "redressement." Inasmuch as aerial photographic mapping promises to be an important peace-time application of photography we publish a translation of the text of his paper.—Eds. "B.J."]

1. *Introduction*.—A photograph having been made on a plate not in a horizontal plane, the object of "correction" is most commonly the projection of the negative on to a photographic sensitive surface under conditions such that the sharp image obtained is similar to that which would have been obtained directly on a horizontal plate for the purpose of simplifying map-making work, or even of forming a map by the assemblage of the corrected photographs. The same descriptions of manipulation are plainly applicable to the case of the correction on a vertical plate of panoramic photographs made on an oblique plate for the purpose of the production of a cartographic canvas and of the determination of level, all measurements of azimuthal angles or heights being very much simpler on vertical negatives than on oblique negatives.

The question of correction has been studied for a particular simple case, namely, its application in architectural photography, by C. Welborne Piper, de Romance, and J. Olive, who, by means of different methods of computation, have arrived at the same conclusions.

Corrections of photographic negatives taken from balloons were shown at the International Photographic Exhibition, at Dresden, in 1909, as also the Perspectograph, a correction camera worked out for this purpose by the Austrian army officer Th. Scheimpflug, and which appears to have been used by the German and Austrian armies. Numerous attempts at correction, effected in many cases by empirical methods, were made in the Photographic Sections of the French Army Aerial Service in 1915 and 1916.

to coincide, the plane of this figure being the principal vertical plane of the taking lens into which we will bring the optical axis O A of the correcting lens, the plane of the figure thus forming a symmetrical plane for the whole system in question.

From S draw a horizontal plane and from O a plane parallel to the plane of the new projection. The intersections of these planes by the plane of the figure are S H and O H. These planes meet along a straight line H D, the intersection of which is H. Let us consider, in the plane T of the map, a straight line a, d , defined by its angle δ with the intersection of the plane T and, represented by its revolution round a, d_1 , viz., a, d_1 in the plane of the figure.

In order to determine the image A D of this straight line, produced by the lens S in the plane P M, we will first draw through S a parallel to a, d . This straight line, contained in the horizontal plane S H D, cuts the plane O H D at a point D of H D defined by its revolution D_1 round S H. The angle H S D, being equal, by construction, to H S D, the image of a, d in the plane of the negative is the straight line A D, the revolution of which, A D_2 round A H, is obtained by joining A to the point D_2 situated on the perpendicular at H to H A at a distance $H D_2 = H D_1$.

The image of A D projected by the lens O on the plane, drawn by M A' perpendicularly to the plane of the figure, is a straight line A' D'. The straight line O D being parallel to the plane of projection, the image D' of D is displaced to infinity in the direction D O, the revolution D_3 O of which around O H is obtained by setting off on the perpendicular drawn from H to H O a segment H D₃ = H D₂ and joining D₃ O. The straight line A' D', parallel to D O, will thus be defined by its revolution the line A' D'₁ round the intersection M A' of the plane of the corrected image, the angle H' A' D'₁ being equal to the angle H O D₃. Calling this angle Δ' the triangles H S D₁ and H O D₃ give us respectively:

$$H D_1 = S H \tan \delta. \quad H D_3 = O H \tan \Delta'.$$

Since H D₁ and H D₃ are equal, being both equal to the same segment H D:

$$\tan \Delta' = \frac{S H}{O H} \tan \delta \quad 1.$$

TONING P.O.P. PROOFS WITHOUT GOLD.

(From: Rajar "Trade Notes.")

This month we offer our professional friends a suggestion as regards the toning and fixing of P.O.P. proofs. It is a debatable point as to whether they should be sent out fixed or not, but we are inclined to recommend that they be fixed. So far as we can see, the only reason for sending out unfixed proofs is to defeat the "something for nothing" customer. It is a fact that, in spite of the customary caution sent with unfixed proofs, the sitter invariably exposes them freely to daylight until the images appear flat and foggy. This may militate against a good order; indeed, it often results in dissatisfaction and a request for a re-sitting.

We suggest that the proofs be printed rather deeply and immersed in a combined toning and fixing bath that will give a pleasing warm tone with full gradation but imperfect fixation. A P.O.P. proof treated in the bath given here will retain its colour and brightness for several months, and, as no gold is used, the process is inexpensive.

LEAD TONING AND FIXING BATH

Acetate of Lead	1/2 oz.
Hypo	4 oz.
Water	20 oz.

The P.O.P. proofs are printed fairly deeply and immersed direct in the above bath for from 3 to 5 minutes. The colour produced is a rich warm brown, free from yellowness, with pure high lights. A short wash in water completes the process. The used bath can be saved and used over again much in the same way as the hypo-alum bath for toning bromides, and replenished occasionally with new solution. A new bath has a greater reducing action than an old one, and the tones are warmer.

If self-toning paper is used for proofs, this bath gives with our "Autona" paper a very fine brown tone, quite free from double tones or yellowness.

We do not, of course, recommend this toning bath for ordinary work, as the prints gradually undergo a change of colour, and cannot be considered as permanent.

Exhibitions.

BRITISH SCIENTIFIC PRODUCTS.

THE exhibition which is being held at the Central Hall, Westminster, until August 5, is a very great advance upon that which was brought together a year ago at King's College and afterwards at Manchester. This year firms are released from the necessity of secrecy which prevented their exhibiting their goods during the period of the war, and the result is that, particularly in the spheres of engineering, chemistry, and electrical appliances, the exhibition is the most striking demonstration of the additions to our industry which the isolation of this country during the past five years has occasioned. The most non-technical visitor is bound to be impressed by the fact that in scores of instances British firms are now making appliances and materials which previously were obtained from the Continent, or in many cases are making something better. The descriptive catalogue, under the editorship of Sir Richard Gregory, chairman of the exhibition organising committee, is a great deal more than a guide to the exhibits. In a series of articles it is a wide survey of the work done during the war and for the war in the industrial and scientific fields by the universities, the importance of which to the industrial community cannot be too strongly emphasised. The catalogue also provides a rapid review of the organisation which has been accomplished for industrial research, in a number of instances by individual firms and in others by trade associations, of which the photographic trade is one. As is pointed out, upon this research the development of the scientific industries which have made so great a beginning amid the distractions of war very greatly depends. We can recommend a perusal of the catalogue to all those who would learn what has already been done, and how much still remains to do, in these developments of manufacture which for the most part are new to this country. The catalogue is issued by the British Science Guild, 199, Piccadilly, London, W.1, price 2s. 6d.

Of exhibitors among the photographic trade there are a considerable number, although the photographic optical firms are represented almost more by non-photographic instruments than by photographic lenses. Messrs. Taylor, Taylor and Hobson are the chief exhibitors of lenses employed in aerial photography, and exhibit a few extremely good military photographs made with the Aviar lens. Messrs. Aldis Bros. show the long-focus lenses specially designed for the photography of Zebrugge Harbour from a great height. Messrs. Ross, Limited, exhibit specimens of the Aero Xpress lenses of f/5.6 and f/4.5 aperture, the former one of their later developments during the war for the making of photographs on 18 by 24 c.m. plates. Messrs. R. and J. Beck's exhibit is chiefly devoted to the sights, telescopes, and periscopes, to which their resources were chiefly applied. Messrs. J. H. Dallmeyer, Ltd., show a selection of their optical specialties, and Messrs. W. Watson and Sons, Ltd., exhibit gun-sighting telescopes and prism binoculars. Of the manufacturers of sensitive material, the two exhibitors are Messrs. Hford, Ltd., and Messrs. Illingworth and Co. The Hford exhibit, in addition to including spectrograms of sensitive dyes and the firm's new panchromatic plate, makes a prominent feature of the tropical hardening solution recently reviewed in these pages, and contains also some specimens of the orthochromatic visual light-filters recently described by Mr. Reuwick in his paper before the R.P.S. Messrs. Illingworth give special prominence to their work in the baryta-coating of raw paper base, to the special papers manufactured by them for the Royal Air Force, to their paper for direct X-ray photography, and to the facilities of their factory in the manufacture of the 54 ins. bromide paper, which has been used for many of the large battle pictures shown in the various war photograph exhibitions. Messrs. Johnsons make a prominent exhibit of the developers, metol, glycin, amidol, pyro, and others manufactured by them, and of their many preparations in the form of compressed tablets and packets for photographic use. The exhibit of Messrs. Johnson, Matthey and Company is of the precious metals and their salts, and of later developments in the manufacture of tungsten, thorium, and other compounds which have lately assumed great importance in British industry. From this brief review, we should not omit to mention the exhibit of the Westminster Engineering Company, of arc lamps for projection and

enlarging, nor that of Messrs. Flatters and Garnett of microscopical apparatus and preparations. Although we have singled out simply the exhibits of photographic firms, the exhibition as a whole is an eloquent tribute to the value of photography, for in the case of a very large proportion of the exhibits use is made of photographs and of photo-micrographs for demonstrating the quality of a product, the character of a machine, or the perfection of a process.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents have been received between June 23 and 28:—

- FOCAL-PLANE SHUTTERS. No. 16,000. Focal-plane shutters. E. C. Bass.
- FRAMES.—No. 15,738. Photograph frames. E. Green and A. E. Jones.
- STEREOSCOPES.—No. 16,261. Stereoscopes. J. M. Hattersley.
- CINEMATOGRAPHY.—No. 16,155. Cinematograph studio cameras. W. E. L. Day.
- CINEMATOGRAPHY.—No. 16,156. Cinematograph projectors. W. E. L. Day.
- CINEMATOGRAPHY.—No. 16,157. Cinematograph apparatus. W. E. L. Day.
- CINEMATOGRAPHY.—No. 16,013. Cinematographs. S. Meyer.
- CINEMATOGRAPHY.—No. 16,153. Cinematography. H. L. Milner.
- CINEMATOGRAPHY.—No. 15,954. Cinematograph projectors. T. Royle and W. Whitehead.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

TRANSFER BROMIDE PAPERS.—No. 126,149 (May 7, 1918). The invention is for improvements in manufacturing photographic transfer paper of the character described in the specifications of F. W. Kent and T. P. Middleton's patent No. 12,091 of 1915 (B.J., Oct. 13, 1916, p. 560, and of F. W. Kent's No. 29,616 of 1912 (B.J., Feb. 13, 1914, p. 126); these improvements conducing to better industrial manufacture and to an improved product.

It has been found to be desirable to separate the operations of coating the waxed paper base with substratum and coating with emulsion. The following advantages are thereby secured:—

1. There is no large mass of heated wax at that end of the coating room which it is desirable to keep cool.
2. There are no fumes from the wax and substratum in the closeness of the dark coating room.
3. It is possible to prepare the base so that it shall be ready for coating by other manufacturers without the aid of special machinery.

This is made possible according to the invention by the use of a substratum which on drying leaves deposited grains, in the hereinafter mentioned examples an amorphous powder, bound or tied together by a varnish medium. The powder in the substratum may be in suspension or in solution, or partly in suspension and partly in solution.

To produce the most effective result the resinous substratum or interstratum is a resinous complex in which grains of one resinous constituent stand out in grains in a film of the other resinous constituent, the texture of this complex of two species tending against such strains and stresses in the film as may induce towards self-stripping.

To produce the required resinous complex, the principle of the well-known matt varnish of the photographer is brought into service. Two resinous materials (as sandarac and mastic) are required, also two solvents (as ether and benzene). The action may be by the deposition of one resinous constituent in grains following

the evaporation of the more volatile constituent of the mixed solvent; the deposited grains being insoluble in the remaining solvent.

The sandarac being insoluble in benzene, the grains of sandarac are precipitated by the evaporation of the ether, whereas mastic is freely soluble and remains as a varnish.

The use of two resinous constituents does not necessarily involve the use of two commercial resins, as certain commercial resins which are available for the purposes of this invention contain two constituents. It is, however, generally preferred to control the effect by the use of two definite resinous substances.

In general, it is preferred that the original substratum should be a solution or nearly complete solution, as the powder thereby obtained is much finer in the grain and more even than if held merely in suspension.

The solvent must contain two or more components, one of which must be a good solvent for wax, and the other of which should have little or no solvent action; but the former must not be too free a solvent.

In addition, the wax solvent component must be the more volatile of the two. The wax non-solvent component may be a water soluble alcohol, e.g., ethyl or methyl alcohol or a mixture of these, and the wax solvent component may consist of dimethyl, methyl-ethyl, or acetic ethers or their homologues.

In general, such a substratum will contain two solids, both soluble or almost soluble in the mixture of liquids, but one insoluble or nearly so in one of the solvents; so that as drying takes place a resin is precipitated, while another dries as a varnish. Water will often be found to facilitate this action, as some bodies which are soluble in alcohol are not soluble to the same extent in 90 per cent. alcohol.

Occasionally the substratum will appear to only contain one solid, as in the case of gum elemi, one form of which, though completely soluble in ether-alcohol, is only partially so in alcohol; there being two or more constituents.

All must be chosen as have no deleterious action on a sensitive emulsion. Mastic, sandarac, dammar or like gums will, in general, be found to provide the most serviceable substrata.

The proportion of the partially insoluble body to the completely soluble body gives the control over the grain desired; since the grain will be finer as this proportion is made smaller. The grain may be as fine as possible, and the degree may be varied to suit the surface of the paper; thus the grain may be coarser as the paper is smoother, and *vice versa*. In addition, the total amount of solids in the substratum should be no more than is required to secure proper adhesion.

The proportion of solvents present will also have some influence on the grain, but in general these solvents will be chosen to suit the conditions of waxing; and these conditions are dependent upon the nature and porosity of the paper, the temperature at which waxing takes place, and the time the paper remains in the wax. One of the great advantages of this invention is that these conditions are now rendered independent of the coating running speed; and so wider variation is possible in the nature and thickness of the paper; and, if necessary, the temperature of the wax can be near the boiling (or dissociation) point and the time much prolonged; so that very perfect waxing is possible. The ease with which stripping takes place partly depends on the solvents used and the proportions in which the solvents are present; and such a mixture must be selected as will give good facilities for stripping, while avoiding any tendency to "self or automatic" stripping. The more perfect the waxing, the greater must be the affinity of the solvent for the wax.

Care must always be taken that no impurity is present in the solvents which, if left on evaporation, would have a deleterious effect on the subsequent emulsion coating.

The following are examples of possible variations.

A. Sandarac	90 grs.
Mastic	20 grs.
Methylated ether, .720 sp. gr.	3 ozs.
Methylated alcohol, 90 per cent.	3 ozs.

The paper base being a "plain paper" prepared for photo-

graphic purpose, weighing 90 gms. per square metre; the temperature of waxing being 250° F., and the running speed 12 feet per minute.

This gave a very satisfactory product, with easy stripping and no tendency to "automatic" or "self" stripping when the emulsion coating was thin.

B. In another example, where a thinner "plain paper" not prepared for photographic purposes and of very inferior quality was used, being that in use for lining shelves, etc., weight about 75gms. per square metre, temperature of waxing about 220° F., and running speed 10 feet per minute, the waxing being more perfect than in the previous example, the following was used, and gave results comparable to example A. :—

Sandarac	90	grs.
Mastic	20	grs.
Alcohol, 90 per cent.	4½	ozs.
Acetic ether (anhyd.)	1½	ozs.

In this example B the substitution of acetic ether for methylated ether, the former having a greater affinity for the wax, enables perfect adhesion to be realised, notwithstanding the more complete waxing of the paper.

The formula in example B is one which will also serve for the conditions of waxing and class of paper set forth in relation to the formula in example A if the emulsion coating is to be thick and the amount of gelatine present is to be greater.

Wide variation from the above exemplars is allowable, as the pull of the substratum on the wax must be adjusted to the pull of the gelatine layer.

This pull depends,

1. On the thickness of the layer, which, again, depends,
 - (a) on the amount of gelatine present in the emulsion;
 - (b) on the method of coating, i.e., whether by dipping, kissing, wiping, or so forth;
 - (c) the running speed.
2. On the presence or absence of hygroscopic bodies either added intentionally—e.g., glycerine; or unintentionally—e.g., nitrates left by imperfect washing.
3. On the nature of the original gelatine—i.e., whether hard or soft, and on the amount of chrome or other alum added (if any).

Whether the substratum and coating operations are carried out separately, as in general is preferred, or are carried out as a continuous operation, as may in some cases be required, some departures from the machine described in the later of the herein above-mentioned specifications are advisable in view of the more volatile nature of the substratum, according to the present invention this increased volatility tending towards undesirable clogging and consequent unevenness in the coating, and trouble in drying.

To avoid these difficulties, and, in general, to promote easy manufacture, the machine illustrated diagrammatically in the accompanying drawings will serve.

In the drawings, a designates an electrically-heated waxing dish in which paraffin wax is kept at a temperature of about 250° F. A paraffin wax having a melting point of 132°-134° F. will serve. The paper b from a supply roller c is led back and

forth more than once through the wax. On leaving the wax the paper passes between doctors or rollers d, d for removing excess of wax. Thence the paper passes upwards to be buffed or

polished by passing between a roller e and a polishing buff or brush f which revolves at a speed much higher than the surface speed of the paper, a working example being: peripheral speed of the buff, 1,500 to 2,000 feet per minute; surface speed of the paper, 10 to 12 feet per minute. After buffing, the paper passes through a substratuming dish g, and then through a horizontal drying trunk or chamber h. This trunk h is heated, as, for example, with a hot water coil i, and air is exhausted therefrom by means of a fan or the like, thus preventing the fumes going out in the room. The substratuming apparatus may also be covered in, and made subject to the exhausting action.

The substratum is applied by two rollers j, j in contact, the roller dipping in the coating trough running anticlockwise and in contrary sense to the other roller, and the superfluous substratum being, if necessary, removed by means of a wiper k, which may consist of two thicknesses of flannel folded round a lath. A weight (or spring) l gives the necessary pressure.

All the paper-web bending rollers are driven at the surface running speed. On leaving the drying chamber the paper passes to an ordinary rewinding machine if the substratuming and coating operations are to be carried out separately. Otherwise, as a continuous operation, the paper b goes to an emulsion coating device m of ordinary type, and, after coating, is carried through a cooling chamber n by means of endless tapes o running at a speed considerably faster than the surface running speed. Cold air may be blown into the chamber in this case. On emerging from this chamber the paper b passes to a suitable looping machine for drying. Kerotype, Limited, 106A, Upper Tooting Road, London, S.W.17, and Thomas Percy Middleton, of 127, Tooting Bec Road, London, S.W.17.

CINEMATOGRAPH FILM SPOOLS.—No. 120,213 (October 21, 1918). The present means of attaching the films to the spools is, when the boss of the spool is made of wood, by placing the end of the film underneath a spring fixed to the boss and when made of metal such as thin tubing, by inserting the end of the film into a slot formed in the boss, then turning the spool round a few revolutions to ensure film gripping, both these means are comparatively slow, there is also a great probability of scratching the film or breaking off the end; the objects of this invention are to provide means for facilitating the mounting of films upon the spools, more especially when renewing the same during operating, by which they may be instantaneously attached to and released from the spools, also to eliminate the risk of damaging the films.

The invention consists in fixing on the wooden boss of a spool a sheet plate provided with two rows of teeth by stamping the same and spaced to correspond with the perforations (usually termed sprocket holes) on each side of the film; or inserting in the boss two rows of pins, screws, nails, or such like to serve as projections for engaging with the perforations on each side of the film.

In spools having a sheet metal boss by fixing on same, by soldering or otherwise, a sheet metal plate as above described or stamping the teeth out of the boss itself.

Arthur Laban, c/o Will's Hotel, Mackay, in the State of Queensland, Commonwealth of Australia.

FORTHCOMING EXHIBITIONS.

September 13 to October 11.—London Salon of Photography. Entries close September 2. Hon. sec., 5a, Pall Mall East, London, S.W.1.

October 13 to November 29.—Royal Photographic Society. Secretary, J. McIntosh, 35, Russell Square, W.C.1.

ENEMY PATENTS AND TRADE MARKS.—The Board of Trade have issued a General Licence authorising the payment of fees in respect of the grant and renewal of patents, and of the registration and renewal of the registration of trade marks and designs in enemy countries or on behalf of enemies.

A READER FROM ———DON, who on June 11 wrote to Messrs. Hood and Company, Limited, Middlesbrough, but without giving either his name or address, is asked to communicate in a form which permits of a reply. The indication given above of the town from which he writes is all that can be deciphered from the postmark.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JULY 12.

- Huddersfield Naturalist and Photographic Society. Excursion to Castle Hill.
 Chelsea Photographic Society. Outing in Jefferies' country.
 South London Photographic Society. Excursion to Bank Side and City.
 St. Clements Press Photographic and Rambling Society. Outing to Hampton Court, Esher to Kingston.
 Hackney Photographic Society. City Outing.

TUESDAY, JULY 15.

- Hackney Photographic Society. "Exposure." J. Linley.

WEDNESDAY, JULY 16.

- Tunbridge Wells Amateur Photographic Association. "Colour" Exhibition.
 North Middlesex Photographic Society. "Work on the Negative." J. Harbert.

THURSDAY, JULY 17.

- Hampshire House Photographic Society. "Hints from Cine Photography."

CROYDON CAMERA CLUB.

MR. H. GUY JOHNSON gave a capital exposition on "Reposé Copper Work," one of those non-photographic subjects welcomed in the summer recess.

A comparatively new member, he almost instantly acquired the status of the elect, and by recently presenting the club with a new blackboard, or, rather, "greenboard," which, without squeaking, receives graphic curves and equations, and presents them with great distinctness, he has added materially to the discomfort of many. With the old board, only at certain angles could chalk inscriptions be seen, and what cannot be seen obviously need never be noticed; but now the case is different, and common politeness compels attention, and often a fraudulent aspect of understanding hard to maintain.

His first step after joining the club was to effect important improvements in the paraphernalia connected to the erratic alternating projection arc, which instantly resulted in the fuses blowing. Since then, he has reduced it to abject submission, and, in his hands, it burns steadily with hardly a note of remonstrance. This is a remarkable achievement, and when it is mentioned that the improvements alluded to will effect a saving in current of at least sixpence a year, the value of a practical electrician as a member becomes apparent.

As regards the reposé work executed by the versatile artist, all that need be said is that he successfully chased some chaste designs, and explained every step in the process, which is hardly one which will appeal to those subject to headaches. Several other members, unasked, also lectured on the art, and gave the principal performer long periods of rest. A most hearty vote of thanks was accorded him.

Talking about reposé work, brings to mind that the new landlord of the club—the Phoenix Assurance Co.—has recently taken down the outside notice-boards advertising the club, and replaced them by ornamental lettering advertising the company. As compensation, it has dealt with the rent in an opposite direction, and the entrance and staircase leading to its offices, and the club-rooms above, have been converted into things of real nobility—using the word in a modern sense. A refinement consists in fitting swing-doors in close proximity to the front door, which, as usual, opens inwards, and every care must be taken to close the latter before negotiating the former, or there is a decided mix-up. Should a member, closely following, endeavour to re-open the front door before the gentleman inside has cleared the swing-doors (which has occurred more than once), the language that will proceed from within will convey to the last comer that something is seriously wrong, but, possibly nothing beyond. Accordingly, intending visitors might kindly make a mental note that the correct procedure in such a contingency is to restore the front door to the closed position and wait for their turn. To attempt to enter while the concert is on only aggravates the evil.

Commercial & Legal Intelligence.

NEW COMPANIES.

REGINALD E. CARTER, LIMITED.—This private company was registered on June 30, with a capital of £6,000 in £1 shares. Objects: To acquire the business of wholesale dealer in photographers' requirements carried on by R. E. Carter, at 12, Lower Seymour Street, W.1. The subscribers (each with one share) are:—R. E. Carter, 12, Lower Seymour Street, London, dealer in photographic requirements; J. F. Remington, 46, Cherry Street, Birmingham, C. A. Director, R. E. Carter. Solicitors, Gem and Co., 2, Bennetts Hill, Birmingham.

KAPPA WORKS, LIMITED.—This company was registered on June 26, with a capital of £30,000 in 29,990 Ord. shares of £1 each and 200 founders' shares of 1s. each. Objects: Manufacturers of and dealers in photographic sensitive papers, baryted bases, and photographic chemicals, apparatus, and accessories, &c. The subscribers (each with one Ord. share) are:—J. R. N. Rae, Ortania, The Esplanade, Thorpe Bay, Essex; E. G. Todd, 73, Boyne Road, Lee, S.E.13, traveller. First directors to be appointed by the directors. Registered office: 2, Verulam Buildings, E.C.

LENS MANUFACTURERS' SUPPLY CO., LIMITED.—This private company was registered on June 27, with a capital of £3,500 in £1 shares (2,000 Pref.). Object: To carry on the business of optical, surgical, cinematograph, and general engineers, machine-tool and accessory manufacturers, &c., and to enter into an agreement with F. Gibbons and S. Hughes (trading as the "Balham Engineering Co."). The first directors are:—F. Gibbons, 29, Chairview Road, Streatham, S.W.7, engineer; S. G. Hughes, 37, Longbeach Road, S.W.11, insurance broker. Registered office, 10a, Trinity Road, Balham, S.W.17.

News and Notes.

HOUGHTON PRICE REVISIONS.—Messrs. Houghtons, Limited, 88/89, High Holborn, London, W.C., have issued a 24-page pamphlet itemising revisions of prices as compared with the 1914 general catalogue issued by them, as well as with lists subsequently issued. The pamphlet also indicates goods which have been withdrawn.

PERMANENT CINEMATOGRAPH FILM COLLECTIONS.—In the "Times" of Wednesday last, July 9, Mr. Herbert G. Ponting writes in contradiction of the view recently expressed by a writer on cinema topics in the "Times" to the effect that an obstacle in the way of preserving motion picture records is that of preserving the films themselves in good condition. Mr. Ponting instances, in support of his contention, the Scott Antarctic films, which underwent two journeys through the tropics, once before development and afterwards on their return, in addition to experiencing low degrees of temperatures down to 50 or 60 below zero Fahrenheit. This was in 1910, and Mr. Ponting mentions that these films, although subjected to the severest of tests, yield positives which for brilliance and quality are indistinguishable from those made immediately on his return from the expedition. He is prepared to take the view that film negatives properly treated with glycerine and hermetically sealed should last for at least 100 years.

A BUTCHER-WILLIAMSON CINEMATOGRAPH ARRANGEMENT.—Messrs. W. Butcher and Sons, Limited, have completed an arrangement with the Williamson Kinematograph Company, Limited, by which they have secured the sole distributing rights throughout the world for the manufactures of the latter firm. Messrs. Butcher, moreover, have taken a financial interest in the Williamson Kinematograph Company, and Mr. W. F. Butcher has joined the directorate of the Williamson firm. The arrangement is one which allows Mr. Colin Williamson, well known as a mechanic and designer of all descriptions of cinematograph appliances, to devote himself exclusively to the manufacturing side of the business. Messrs. Butcher have purchased the lease of the Williamson Company's premises at 28, Denmark Street, London, W.C., and will employ them as their West End branch as soon as the necessary equip-

ment in the shape of showrooms, projection demonstration theatre, stores, and repair shop has been completed. The branch will be under the management of Mr. N. E. Barber, for some years Mr. Williamson's assistant manager. A combined catalogue of the principal manufacturers of the Williamson company and of Messrs. Butcher is in the press, and will be ready for distribution to the cinematograph trade very shortly.

A SPEAIGHT GARDEN PARTY.—The employees of Messrs Speaight, Limited, were entertained at a garden party given by Mr. and Mrs. Richard Speaight, at their beautiful home at Beaconsfield, Buckinghamshire, on Saturday last, July 5. A programme of sports, in which a one-legged New Zealand soldier distinguished himself, entertained the company during the early part of the afternoon. Messrs. Speaight had invited also a few Colonial soldiers, who, owing to the loss of limbs, were unable to carry on their pre-war employments. After tea, to which nearly sixty sat down, Mr. Richard Speaight heartily thanked the staff for the splendid services which they had rendered during the war. The firm was proud of the fact that every male member of military age had offered himself for active service when the Government asked for volunteers in 1915. They regretted that two of them had been killed; others they were glad to welcome back in their old places, and the firm could not sufficiently thank those who had carried on its work during the past difficult years. Mr. Speaight welcomed the presence in the party of some heads and representatives of photographic firms, and expressed his appreciation of the help and courtesy which his firm had received from them during the period of the war. Mr. Gerald Bishop, of Messrs. Marion and Co., in responding, expressed his pleasure at being present. His firm, he said, could speak of friendly relations with that of Messrs. Speaight for twenty-five years. Mr. Cullun, of the Kodak Company, referred to a similarly cordial relationship between his own firm and that of Mr. Speaight. An impromptu concert, given by members of the staff, greatly contributed to the enjoyment of the day, and the proceedings ended with a vote of thanks to Mr. Russell Sellar for his arrangement of the sports and for his own clever conjuring and thought-reading entertainment. A train in the late evening bore the party back again to London, after a supremely pleasant day.

Correspondence.

- *.* We do not undertake responsibility for the opinions expressed by our correspondents.

A PROFESSIONAL PHOTOGRAPHIC ASSISTANTS' ASSOCIATION.

To the Editors.

Gentlemen,—Re the formation of a Professional Photographic Assistants' Association, in the report ("B.J.," of June 27) of the meeting of the P.P.A., I note that it was suggested, and the committee approved of such, and it was carried that they would give financial assistance to the sum of £10. As an assistant of many years' experience, I think it was the only and by far the wisest course to take. I should like to thank the committee for the great interest they have taken in the question.

It now remains to be seen if the assistants have any real interest in the profession, for if such an association comes to life, it cannot fail to be of great benefit to us and the profession as a whole. I feel the time has now arrived to make a start in this direction, and would like to suggest that any assistant interested in its formation who can attend a meeting in London (at a date to be decided) to enable a committee to be formed, to frame rules, programme, &c., would kindly communicate with me at the very earliest. I will at once do my best to arrange such a meeting. Now, assistants, it is for us to act, and act at once.—Yours truly,

A HAMILTON SMITH.

64, Marine Parade, Hythe, Kent

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

- R. F. O.—The Defence of the Realm Order dealing with photography out of doors has been repealed since the armistice was signed, so that you may use your camera as freely as before the war.
- E. C. D.—The negative sent appears to have partly melted on the surface; we have seen several such cases during the recent hot spell. The foggy appearance is probably also due to the same cause. The only preventive is to cool the developer by means of ice.
- G. C. H.—Almost any lens which will give good definition will answer for outdoor portrait photography. A rapid rectilinear is perhaps the most suitable, but whatever kind is chosen, it should not be of too short focus. Ten inches is a good length for half-plates.
- H. A.—If your friend ordered and paid the usual charges for the photograph, then the copyright belongs to him; he can give you permission to make enlargements from it if he wishes, and there is nothing to prevent him from exhibiting the enlargements in his window.
- H. J.—Waste sodas or hypo are of no value as fertilisers. The best suggestion we can make is that you keep the waste carbonate as a substitute for washing soda for domestic purposes, whilst the hypo and sulphite may be used as deodorisers—for example, in flushing sinks, &c.
- F. M.—You can get backing colour ready prepared from any large dealer in photographic materials. It has simply to be spread on the back of the plate, either with a soft brush or a pad of flannel. Do not remove it until the plate is nearly developed, or you will probably spoil the film.
- A. S. B.—So long as you confine your business to wholesale trading there is no need for a licence. The Order applies only to retail businesses, and, in the case of photography, at present includes only those businesses where frames or other accessories are sold. No charge is made for a licence in any case.
- W. E. B.—The stigmatic will answer well for practically any class of work, but $7\frac{1}{2}$ ins. is rather short for half-plate groups, unless they are a good distance from the camera. If they are close up, such as a small wedding group of six or eight figures, the front ones will be rather too large in proportion to the back ones.
- W. S.—The direct vision finder can be fixed in a minute or two by the aid of two screws. The usual angle embraced is about that for the $5\frac{1}{2}$ ins. lens on a $\frac{1}{2}$ -plate, but by putting the eye a little nearer it would probably do for the $4\frac{1}{2}$ ins. as well. You can get such finders from any of the large photographic dealers.
- C. D.—The Autotype Company, 74, New Oxford Street, London, W., make a photogravure tissue which acts as a resist, and they will send you all particulars as to its use. For relief blocks, bichromated fish-glue is used as a resist. Asphaltum is rarely used nowadays. Block-making requires much skill, and the apparatus is rather costly.

F. O. C.—Just now there seems to be no uniform system of marking retouching leads. Some makers do not mark them at all, but will supply them in various grades corresponding to the old numbers, which were No. 2, soft, No. 3, medium, and No. 4, hard. Others mark them with the ordinary HH to BB, like the cedar pencils; of these, HIF and HB are the most useful.

T. C. P.—You are using altogether too much light. In addition to the white blinds you want a set of dark ones with which you can stop out all light from the greater part of the roof and side. Also, the interior of a studio which faces the sun should never be painted a light colour; a medium grey or sage green would greatly help to do away with the flat effect.

C. H.—The proportions of the fixing-hardening bath seem about right. Probably the tendency of the bath to deposit a sludge is caused by a wrong method of mixing the chemicals. You should dissolve the alum and sulphite in separate solutions. Cool these if you have used hot water, and then add weak acetic acid to the sulphite, then add the alum solution to the mixture. When this mixture has been made it is then added to the hypo solution.

G. W.—We doubt if the performance of the lens is wholly due to deterioration of the surface, but, at any rate, such deterioration, if really marked, will account for a great deal. It all depends on the condition of the surface whether re-polishing can be done. Re-balsaming, of course, is simple enough, and an optician could say at once whether that would effect any remedy. Usually it is difficult to get the standard lens makers to do repairs of this kind.

D. F.—Three 1,000 c.p. lamps of the ordinary half-watt pattern should give you sufficient light; each of these should have a white reflector behind it, and a thin calico diffuser in front. The lamps should be placed about 8 ft. from the ground for standing figures, but should be able to be lowered to 6 ft. for sitting figures and children. This will greatly shorten the exposure; in fact, halve it. The walls should be a light colour, but not white, as this tends to flatness.

A. A.—1. Any assistants who come in contact with customers are within the scope of the Shops Act, and can demand the weekly half holiday, whilst the fact of their being engaged in the place makes the half-day closing compulsory unless relief is obtained from the local authority. You should apply to your municipal authority, town council, or district council, for particulars. 2. Messrs. Hood and Co., Sanbride Works, Middlesbrough, can supply calendars of the kind you mention.

T. W.—An enlarger is designated by the largest size which the condenser will cover—for example, a 5½-in. condenser will only illuminate a quarter-plate, and a 8½-in. condenser a half-plate. You can enlarge from any smaller plate than these; thus a half-plate enlarger will take all the smaller sizes you mention. As an example, we have recently been enlarging 1 in. by ¾ in. in a whole-plate enlarger. The size of the enlargement is limited only by the strength of the light you employ.

F. A. C.—1. We think that you will get very little colour correction by using the sample of glass sent. If you want a cheap and good screen, get a piece of K2 gelatine film from Kodak and place it between your lenses. No glass will then be necessary. The regular ortho plates should be used; ordinary plates gain practically nothing from the use of a screen. 2. The commercial red and green glasses vary so much in quality that no comparison is possible. The Wratten safe-light No. 2 will be the safest investment.

J. R.—The Morrison lens, of which you send sketch, is certainly not of the rectilinear form, but some early type of doublet which we cannot identify. It is very difficult to say anything about these old lenses, as very often the original glasses have been replaced by some later by way of experiment. The lens in no way resembles the Dallmeyer D lenses, which are of exactly the same construction as their patent portrait lenses. We believe Dallmeyer made a few rapid triplets which he called D group lenses before the patent of 1866 was taken out.

A. L.—There are no books on professional portraiture with the exception of such special small manuals as "The Portrait Studio," "Commercial Photography," and "Sketch Portraiture." The best general text-book of principles and practice is the "Science and Practice of Photography," by Chapman Jones, at present out of print, but no doubt obtainable from Messrs. Foyle, 121/123, Charing Cross Road, London, W.C.2. An alternative is "Photography and Its Applications," by Alfred Watkins, the second edition of which has just been published by Messrs. Constable, 10, Orange Street, Leicester Square, price 10s. 6d.

C. B.—The safe-light corresponding with the degree of illumination referred to in the article which you quote is one such as the Series O of the Wratten Division of Messrs. Kodak, Limited, Kingsway, London, W.C.2. This is a very bright light for the handling of rapid plates; but with care in shielding the plate and in keeping it covered during the earlier stages of development, it is quite possible to use it, though in inexperienced hands it would be pretty certain to produce fog. A somewhat darker safe-light is the Wratten Series I. You can buy these safe-lights in sizes 7 ins. by 5 ins. to 20 ins. by 16 ins., and they can quite well be used in a lamp fitted with incandescent gas, unless the construction of the lamp makes the heat altogether excessive.

FIXED-FOCUS ENLARGER.—1. I am making a fixed-focus box enlarger for ¼-pl. to 1-1-pl., according to the formulæ on page 401 of your 1919 Almanac. I have a lens from an eye microscope of about 2 15-16 focus. Will it serve for the purpose, and to what size aperture should it be stopped down? 2. The water here, being used only for washing, is pumped from the river (in the country above York), and is often of a dirty colour from the mud brought down; there is no pollution from factories near here. Is this water suitable for the ordinary purposes of development of plates and papers? If not, can you suggest a remedy?—R. R.

1. If you focus your image with the full aperture of the lens and then fix a stop of about f/45, you will find no real loss of definition on account of the lens not being corrected for chromatic error. 2. Unless there is an appreciable amount of iron in the water there will be no danger in using it. Tie two thicknesses of flannel over the tap to filter out the mud. Swab your plates and paper after washing.

Line Advertisements.

Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.

(No reduction for a series.)

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add ... 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed Adv'ts should reach the Publishers on Monday morning.
The insertion of an Advertisement in any definite issue cannot be guaranteed.

SUMMARY.

In the last of the series of leading articles on stereoscopic photography the writer deals with a by-path, not strictly photographic, but possessing great scientific interest and providing the opportunity for the making of very interesting hand-produced stereograms. (P. 406.)

In the concluding instalment of the paper on the making up of photographic solutions Mr. J. I. Crabtree deals with the purity of water, with common impurities in developing and fixing chemicals, and with the storage of chemicals. (P. 410.)

In his article this week "Practico" deals with the carrying out of such simple repairs and renovation of studio apparatus as come easily within the competency of the photographer. He itemises the outfit which is of service and gives working instructions for carrying out the jobs most frequently required. (P. 408.)

The mathematical conditions for the correction of an aerial negative taken with the axis of the lens at an angle from the vertical have been worked out very fully by M. L. P. Clerc, with the object of providing a rapid means for making from such negatives reproductions representing the results obtained from the same view-point with a vertical lens-axis. (P. 411.)

An interesting case of reversal by the production of dichroic fog on under-exposed plates forced in development is brought to our notice by the Ilford Company. (P. 419.)

The apprenticeship question prompted a lengthy discussion at the Edinburgh Society of Professional Photographers. (P. 418.)

Judgment in the Dublin Chancery Division was given last week in a case of infringement of copyright in photographs. The owner of the copyright obtained an injunction restraining further sales of the photograph. (P. 414.)

The Photographic Convention held its first meeting since the outbreak of war at Oxford last week under the presidency of Mr. G. W. Atkin. (P. 415.)

Rotary gravure, printing on the metal, retouching in photo-litho, and the use of film in process work are among the topics of "Photo-Mechanical Notes." (P. 416.)

The design of a focussing finder of the camera pattern appears under "Patent News." (P. 417.)

Much hypo is wasted by removing prints from the fixing bath without draining. In the course of a day's work a fixing bath may become greatly weakened by addition of developer and removal of hypo, although the fact may escape notice owing to the bulk of the fixer remaining the same. (P. 405.)

Apropos the recommendation of a long-focus lens for good perspective, such a lens is after all only a means of taking the more distant standpoint, which is the decisive factor. (P. 405.)

EX CATHEDRA.

False Perspective. Apropos of our recent note on exaggerated perspective in so many commercial photographs, and the recommendation to use a long-focus lens, it must not be taken that the fact of not having a long focus lens is any excuse for this distortion. Perspective is due to the angle of view, and the angle of view depends on the distance from which any object of a given size is viewed. From any particular position with a long-focus lens you get a larger image than with a shorter focus lens. But whatever the focal length of the lens the photographer should select the point of view that gives a suitable perspective and then photograph. If the image obtained is too small it is almost as easy to make an enlargement as to make a contact print. Of course, we do not ignore the fact that sometimes it is impossible for the photographer to get far enough away from the object, and in that case there is no help for it except to permit some distortion, though if an enlargement is permissible, so that the spectator is compelled to stand in about the same relation to the picture that the camera was to the object, the apparent distortion will not be present.

Economy in Fixing. The price of hypo is still many times that of pre-war times, and various expedients for economising in its use have been suggested. There is one, however, that most people seem to have overlooked, and that is not to pour it down the sink needlessly. We are all apt to work our fixing baths pretty well to the finish, but a good deal of the hypo is wasted before it has done much work. The way in which this occurs is a very simple one—it consists merely of carrying over an excess of the solution into the first washing water. If we watch the ordinary operator we shall find him lifting his negatives and prints in one movement from the hypo to the washing tank or tray, the hypo running in a stream the while. This is especially the case with bromide prints and enlargements, which are often lifted in a mass carrying with them a large quantity of the fixer. If these were lifted separately and drawn over the edge of the dish little would be carried over, and the first washing would be more effective. The loss is often not noticed because the bulk of the fixing bath is kept up by the water which is carried into it by the prints and plates after the developer has been rinsed off. That this is so can be proved by the disappearance of the developing solution. If a man uses up 40 ounces of developer in a day and does not rinse his prints, and many do not, it must have gone somewhere, and there is nowhere for it to go but into the hypo. A fixing bath with 40 ounces of its bulk abstracted and replaced by developer is certainly not in proper condition,

and it is not to be wondered at that the whites of prints "fixed" in it discolour sooner or later.

* * *

Blackening Slides — A caution.

Of the various compounds recommended for blackening the inside of dark-slides, etc., finely ground lamp-black mixed with methylated spirits and a sufficiency of orange shellac to just bind the pigment without imparting a gloss has been considered one of the best and safest to use. A recent experience of a professional photographer, however, points to the necessity of only employing good quality spirit. Some book-form dark-slides were sent by him to a photographic firm to be re-blackened inside, and on their return it was found that plates were fogged all over, even if only allowed to remain in them overnight. Enquiring from those responsible for the job brought an answer that the usual methylated spirits and shellac mixture had been used, and it was suggested that the cause of the trouble was probably due to some new constituent, in the nature of a gum substitute, which had been introduced into the spirit. Certainly much of the spirit lately sold as "methylated" has been wretched looking stuff, and the explanation offered may well be the correct one. A close nasal test applied to the blacking indicated turpentine had not been employed, the fogging propensities of which are well-known.

* * *

Stock-keeping.

Perhaps in a less degree than formerly, but still to a considerable extent, photographers lose money by allowing various articles such as mounts, frames, cases and rims for miniatures, to deteriorate upon the shelves after the first demand has died away. For this reason it is advisable to be very cautious in purchasing, and not to lay in a large stock of anything but standard patterns for which a steady demand is certain. Having the stock on hand, however, the vital consideration is to shift it, so that instead of gradually becoming lumber it is turned into cash, which can work for the business. Every few months it is desirable to look over the stock, and if any one line does not move to clear it out for what it will fetch. For example, there may be half-a-dozen frames of a size and style which do not go with any current work, or an accumulation of mounting papers of

this cannot be done, such old mounts should be passed on to the packer or sent to the mills to be pulped again anything being better than allowing them to occupy space and accumulate dust, without any prospect of their ever being utilised.

STEREOSCOPIC PHOTOGRAPHY.

V.—SOME SCIENTIFIC APPLICATIONS.

QUITE apart from the æsthetic value of the stereogram is its scientific and intellectual usefulness as a method of instruction. So convincingly real is the illusion of stereoscopic vision that a series of stereograms can practically take the place of solid models in many departments of scientific instruction where such aids to comprehension are required.

Almost every object in a museum could be stereoscopically reproduced so as to give nearly as vivid an impression as the object itself. Indeed, the stereogram may in one respect perhaps excel the displayed collection, for while this latter cannot always be lighted to perfection in every part at all times the photographic reproductions may each be prepared under the best lighting conditions, the objects being placed before the camera in the exact positions that will best show the special characteristics of interest. If added to this the knack of seeing stereoscopically without an instrument (already referred to) in acquired an album or cabinet of stereograms might be a veritable museum in itself. In the study of natural history, stereograms are especially helpful. Living organisms and plant forms, small and large, can all be displayed to the life, and nothing but colour is wanting to make the model for all practical purposes as helpful for study as a glimpse of the natural object.

Allusion has already been made to the importance of astronomical stereograms, and to the one or two examples adduced may be added the suggestion that the wonderful models of lunar craters made by Nasmyth and still preserved might advantageously be photographed with the stereoscopic camera pro bone publico. Probably many people who see in text-books of astronomy the superb photographic reproductions of the lunar surface with its craters have never questioned the illustrations as being

A stereogram drawn by the twin elliptical pendulum. By C. E. B.

tint, which no one will now look at. These can usually be sold to a picture-frame maker at a cheap rate, especially just now when stock of all kinds is scarce. With regard to mounts the question is more difficult, as most of these will bear a printed or embossed name and address. It will be economical in many cases to cut up large mounts into smaller sizes, or, where only the edges are soiled, to have them put through the guillotine to freshen them up. If

other than actual lunar photographs. It is disappointing to have to point out that this is not the case, but that these familiar and extensively printed lunar views are generally copies of photographs of Nasmyth's models illuminated by strong sunlight so as to give the correct shadow effects. At the same time the models are so extremely skilfully made that they are well worthy of stereoscopic reproduction.

The application of the stereogram for scientific purposes extends also to photographs of 3-dimensional vibrations and other interesting phenomena in physics. An enormous field is open in the production of hand-drawn stereograms to illustrate such scientific subjects as require either 3-dimensional drawings or solid models. Here we are, perhaps, getting away from photography, but not altogether. So accurate must the perspective drawings be for

point, a second is made at a horizontal distance of $2\frac{1}{2}$ inches, and with the vanishing point shifted in the same direction about $2\frac{3}{4}$ inches. This will ensure that the two drawings shall vary in separation distance between the limits of $2\frac{1}{2}$ inches and $2\frac{3}{4}$ inches, as specified in a previous chapter. The "measuring off" in the second drawing is automatically performed by means of horizontal lines from determining points of the first drawing. This having

these diagrams that it is greatly preferable to execute them on a large scale and then reproduce them photographically, diminished to the proper size for the stereoscope: or the wire models made for the physical laboratory to illustrate such subjects as polarisation of light and crystallography may be photographed direct with the stereoscopic camera.

Hand-drawn diagrams, however, afford more scope than these photographs of wirework constructions, and will enable stereograms to be made exhibiting many important principles which it would be impracticable to imitate by means of solid models. Among these subjects may be mentioned the more intricate forms required to illustrate crystallography, the numerous diagrams needed to expound the principles of polarisation and the theory of perspective. Descartes' theory of the rainbow can be exquisitely rendered in colour as a stereogram, and is one of the easiest subjects to draw. The law of inverse squares is also much clearer in the stereographic than in the ordinary diagram, and many other examples might be given in physics of subjects lending themselves to stereoscopic representation. It hardly need be explained that in drawing stereoscopically all that has to be attended to is the perspective, and consequently subjects should be chosen which consist of ruled lines rather than freehand curves. One drawing having been executed with a given vanishing

been done on a large scale (multiplying the $2\frac{1}{2}$ and $2\frac{3}{4}$, say, by two or by three), the pair of drawings can be copied photographically one-half or one-third their width, and a very perfect stereogram results. Drawing direct without diminution takes a good deal of practice, as extreme exactness is essential, and under the enlarging lenses of the stereoscope is apt to reveal imperfection.

In conclusion, it may be amusing to give one of the curiosities of hand-drawn stereograms—a number of weather vanes which all lie apparently horizontal and parallel, but profess to turn to all points of the compass. The stereoscope shows that their claim is justified, the explanation of the apparent paradox being that they are all drawn at practically the eye level, so that their tilt is only represented by a foreshortening. The foreshortening varies in the perspective of the left and right pictures, and a combination of the images gives by association of ideas the true direction of the arrows. An example is also reproduced of the extraordinary effects obtained by stereoscopic curve tracery executed with the twin elliptic pendulum. The method employed was described in "Knowledge," February, 1914, and it will be seen that here we have presentments of realistic-looking solid curve-forms which never had any actuality, and are never likely to have.

FORTHCOMING EXHIBITIONS.

September 13 to October 11.—London Salon of Photography. Entries close September 2. Hon. sec., 5a, Pall Mall East, London, S.W.1.

October 13 to November 29.—Royal Photographic Society. Secretary, J. McIntosh, 35, Russell Square, W.C.1.

A FOLKESTONE STUDIO OUTING.—A very successful holiday excursion was undertaken by the staff of Mr. Halkesworth Wheeler, Folkestone, on Wednesday in last week, July 12. In company with Mr. Wheeler, his wife, and daughter, a long day was spent by the staff in a motor drive through some of the most picturesque parts

of the coast. Traveling through Tenterden and Cranbrooke, they reached Maidstone for lunch, when Mr. Wheeler took the opportunity of expressing his pleasure at having his assistants again with him after their service in the Army. He looked forward to their prospering together in the business, and the good relationship which existed between them encouraged him to believe in pleasant and profitable years before them. Continuing their motor drive through Wrotham and Cobham, to Rochester, tea at the latter place was made the occasion of a presentation to Mr. Wheeler by his staff of a silver card-case as a token of good will. The return journey to Folkestone was made in the beautiful weather which had prevailed during the whole day, and at 10.30 the party dispersed, after a thoroughly enjoyed excursion.

B

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).
The Postcard Studio (March 14).
The Printing-Room (March 21).
About the Reception Room (March 28).
Home Portraiture (April 4).

Portable Studios (April 11).
Copying (April 18).
Handling the Studio Camera (April 25).
More About Lenses (May 2).
Enlargements (May 9).
Advertising the Studio (May 16).
Mounts and Mounting (May 23).
Business Methods (May 30).
Photographing Children (June 6).
Portraits of Elderly People (June 13).
Something about Lenses (June 20).
Hand Cameras for Professionals (June 27).
The Dark-Room and Its Fittings (July 4).
Plates and Their Work (July 11).

APPARATUS REPAIRS AND RENOVATIONS.

Just now it is not easy to get even the simplest camera repairs done quickly, while the cost, like most other things, is nearly double what it used to be. It is therefore highly desirable that the photographer should be able to help himself when he has a mishap or any part of his apparatus gives out through wear.

Before starting it is very desirable to obtain a few tools, as it is very easy to do more harm than good by trying to make shift with unsuitable appliances. Most of the tools needed are small, and the quality usually supplied to fretworkers will answer very well, besides being less costly than those made for cabinetmakers. I would suggest the following as a start: Two screwdrivers, one of fair size with, say, a 9-inch blade, and one quite small one for flange screws and fixing small hinges. It should be noted that a screwdriver—or, as it is more correctly called, a turnscrew—should not have a sharp edge like a chisel, but should be square at the end so that it fits well into the bottom of the cut on the head of the screw. This is to prevent it jumping out, damaging the screw and perhaps scratching the woodwork. A large bradawl makes a very good small screwdriver if the end is properly shaped, and costs much less than the proper article. Next we want a couple of bradawls, medium and small sizes, the latter being square in section and tapering to a sharp point. This pattern is much better for hard woods, such as mahogany and walnut, as it may be used as a drill, and any risk of splitting avoided. A small Archimedian drill is very useful, as it may be used for metal as well as wood. A quarter-inch chisel, a small hammer and two or three small files will also be necessary, and if the expense be not objected to a small tenon saw and one of the little American steel planes may be added. Although not to be classed as tools, two or three sheets of fine glass-paper will be found almost indispensable, as is also a tube of Seccotine or Le Page's fish glue. For large work and fixing bellows ordinary glue is best, and an efficient glue-pot may be improvised from a jam-pot and a small saucepan; it is desirable to put one or two small pieces of broken glass or china in the saucepan first to allow the hot water to circulate freely under the jam-pot. Screws and nails of suitable size must, of course, be procured as needed, and no risks in using those of too large or too small a size should be taken. It is impossible to deal with my subject in anything like a systematic way, as no two instruments will require exactly the same repairs, so that I will deal with some of the defects most commonly met with.

Looseness of the rack and pinion adjustment, which allows the camera back to move when the slide is inserted or when the bellows is fully extended is usually easily remedied. All that is necessary is to take out the screws which fix the rack to the baseboard and to pack up underneath with strips of brown paper, placed where the loose places were. If the whole length is packed up it may cause some places to fit too tightly. Care must be taken that the screws when replaced have a good hold. If the thickness of the paper prevents this, slightly longer screws must be fitted, or the holes may be plugged with a small peg of mahogany glued in and the holes re-drilled. A good bit of cigar-box wood will do to make the pegs from. Edge-racks in which the teeth are cut on the edge of the strip (like a saw) are more difficult to deal with. With these it is necessary to plug all the screw holes and to make new ones a shade higher so as to bring the teeth into engagement with the pinion. The pinion itself, being usually of steel, rarely needs attention, but if the teeth or leaves of the pinion are damaged a new one must be obtained. These fittings are listed by such firms as Fallowfield, Kodak, and others, and usually only require a touch of the file to adjust them.

Clamping screws sometimes cease to hold owing to the thread being worn. A washer placed under the head will often bring another part of the thread into action. If the plug or nut is worn it must be replaced by a new one, although in some cases a few light blows with a hammer will close it up well enough to serve for a time.

Woodwork is repairable by glue or screws, and I would give a word of caution against trusting to any glued joint which has been allowed to dry without being clamped together until the glue is dry. The less glue that is left between the surfaces the better it will hold, so that we must squeeze out all we can before drying. I am afraid that I cannot give any general instructions for doing this, as the shape of the work varies so much. Ordinary screw clamps as used for holding down sewing machines answer well for two flat surfaces such as the runners on a baseboard; for many other jobs stout strips of wood with small blocks screwed on a little wider apart than the article to be held do very well. The frame, let us say, is glued together, the ends placed between the blocks and thin wooden wedges driven in to give a firm hold. When the wood is thick enough a few small brass screws will add greatly to the strength of the joint.

Small holes and crevices where wood has broken away may be filled with a kind of brown sealing-wax, known to cabinet-

makers as "hard stopping," but it is easier to use a paste made of fine mahogany sawdust and fish-glué. This dries very hard and can be polished over if necessary. Another very useful paste which sets hard is made of dry zinc white, or even French chalk mixed with fish-glué. Cabinet-makers use ordinary glue for stopping compositions, but it has a tendency to get too stiff on cooling to fill the holes easily.

A repair that is frequently needed is the fitting of new velvet in dark slides and the back frames of cameras. This is quite simple if done in the right way, which is to put the glue on the wood and not on the velvet. Ordinary ribbon velvet, to be obtained of any draper is used. This has a selvedge on both sides, which keeps it from fraying. If there is much space to be filled double velveting must be resorted to. This calls for a narrow velvet down the middle of the groove, leaving the wood exposed on each side; upon this a second strip the full width of the groove is placed and well rubbed down. Sometimes one finds a camera or slide fitted with a thick velvet like stiff plush. This is called Utrecht velvet, and as it is not made in the ribbon form the strips must be cut from the piece. In all cases it is necessary that the glue should only be tacky when the velvet is applied. If too liquid it will run into the material and set the pile into a hard mass. The same method of fixing is employed when fitting new flexible joints to dark-slide shutters. The old glue must be scraped off and new glue applied, taking care not to let it run into the joints. The material, which may be strong black linen or thin leather cloth, is then laid on and well rubbed down.

Having done the necessary repairs we can turn our attention to cleaning and re-polishing. I will not touch on French polishing, as it would take too much space to describe, and the details are available in many little manuals. For most camera work the ordinary furniture polishes are sufficient and require no special skill to apply them. If the wood is very dirty and greasy a good rubbing with turpentine will clean it ready for the polish, or the surface may be washed with soap and water. I do not, however, care to wet a camera if it can be helped, so that I recommend turpentine, or if this cannot be obtained, motor spirit or benzole. Methylated spirit or alcohol in any form must not be used, as it will dissolve the polish, as also would ammonia, soda, or any other alkali. A very simple polish, which also cleans the surface, may be made of equal parts of olive oil and vinegar mixed in a saucer and applied with a flannel rubber; when the surface appears to be clean it is polished with a soft duster. A very good polish for cameras and furniture generally is made as follows:—

Raw linseed oil	6 oz.
White wine vinegar	3 oz.
Methylated spirit	3 oz.
Butter of antimony	½ oz.

Mix the oil and vinegar gradually, shaking well, then the spirit and antimony, again shaking.

This mixture gives a good polish with little labour, and does not show finger-marks. It is, so far as I know, the only satisfactory mixture for ebonised woodwork. To leave a nice clean finish it is necessary to rub all mouldings and corners very thoroughly or the polish will collect dust and spoil the look of the article.

A very dilapidated studio stand may be made quite respectable by rubbing down the surface with glass-paper until all scratches and abrasions have disappeared, and then giving two thin coats of black Robbialac, a preparation much used for motor-cars. Your old pine or oak stand will then bloom out as a new ebonised one. The enamel is slow drying, so that the stand should be left over the week-end to dry. It is well to let a week elapse between the two coatings. Head-

rests and other metal goods can be treated in the same way. The Robbialac may be had in various colours, but I prefer the black.

Old lens mounts may be renovated with little trouble. Supposing we have an old portrait lens of which the brass-work has become very black, the first thing to do is to remove the cells containing the glasses and put them away safely. Take off the pinion and slip the jacket off the tube, then rub the jacket flange and hood with methylated spirit to which a little ammonia has been added until all the lacquer is removed. Polish all the brass, including the tube, with rottenstone and sweet oil until the surface is quite bright. If there is much corrosion it may be necessary to use a composition known as "polishing brick," which can be obtained from most drysalts in Clerkenwell or from Coope's in Soho. A little of this is crushed up and mixed to a paste with salad oil and rubbed on with flannel till a good surface is obtained. The flange jacket and hood should then be lacquered, but before doing so any trace of oil must be removed with spirit or by polishing with whiting. Hot lacquering is rather beyond the powers of the amateur, so that it is best to use a cold lacquer which is composed of celluloid. This may be colourless or deep or pale gold colour. It is applied by floating on plentifully with a soft camel-hair brush, and allowed to dry for a couple of hours before assembling the parts again. The inside of the tube should receive a coat of dead black, or what I much prefer a lining of black velvet. The lenses should, of course, be carefully cleaned before returning them to their places.

There is one little job which belongs neither to the wood or metal classes, that is the renovation of the bellows. These often get shabby as well as limp, while the inside loses its pristine blackness and is likely to reflect an undesirable amount of light. It is, of course, easier to handle the bellows if it is taken out of the camera, but this takes time, and as glue is used there is a chance of tearing. The camera must be fully extended and the bellows dusted inside and out with a soft brush, followed by a slightly damp cloth, with which any spots are rubbed to see if they can be moved. Any leaks or doubtful places should now be patched with black silk or other thin close material and Seccotine, and strips of the same applied to any parts which have been badly creased. When the glue is dry the inside may receive a coat of dead black, which may be made of lamp-black and spirit, with enough negative varnish added to keep the black from rubbing off, or, better still, Nigrogene, which is the best black for the inside of cameras and lenses I have yet seen. If the bellows has gone very limp it will be better to mix lamp-black with very thin glue and coat the inside all over. This cannot be satisfactorily done without detaching the bellows so that the folds can be pulled flat, otherwise the glue will run into the canvas and make a mess of the job. The outside may now be treated, and I may say that as a rule I have found it better not to attempt to revive the colour, but to give a thin coating of varnish or even a wax polish like Ronuk, which cleans and brightens the surface. If thoroughly faded it is best to dye the bellows black, and this can easily be done with shoemakers' finishing ink, which can be got from any leather seller in twopenny bottles. This is painted on with a soft brush, and when dry polished with a soft shoe-brush. This leaves rather a smoky polish, but it is a good base for a coat of Cherry-blossom or Nugget boot polish. The finishing ink answers excellently for refurbishing up Kodaks and other hand cameras that have got rusty-looking. A camera which has lost its freshness by being exposed in a window may be freshened up in five minutes, and there is no trace that it has been done, as there would be if varnish of any kind had been used.

HOW TO PREPARE PHOTOGRAPHIC SOLUTIONS.

[In the following paper, previous instalments of which have already appeared, Mr. J. I. Crabtree of the Eastman Research Laboratory, deals in a most explicit and comprehensive way with the practical methods of making up photographic solutions in bulk and with the chemical proportions which require to be taken in accordance with the properties of the substances which are being handled. Although contributed for the information of cinematograph photographers to the "Motion Picture News" there is scarcely a single paragraph of it which does not apply to the customary operations of any photographer working upon a reasonably large scale; and there is, we think, no photographer so fully expert in the compounding of such solutions as developers, fixing baths, etc., who will not get some practical hints from it.—Eds. "B.J."]

(Continued from page 395.)

Purity of Chemicals.

The Water Supply.—Water is the most important chemical used in photography, and it is therefore important to know to what extent the impurities present may be harmful to the various operations and how these impurities may be removed.

Excluding distilled water, rain water, and water from melted ice or snow, the following impurities may be present:

1. Dissolved salts such as bicarbonates, chlorides, and sulphates of calcium, magnesium, sodium and potassium. In case calcium salts are present and a developing formula is used containing sodium bisulphite or potassium metabisulphite, fine needle-shaped crystals of calcium sulphite are apt to separate out in the developer as a sludge on standing. The sludge is harmless if allowed to settle, though the developer is robbed of sulphite to the extent of the amount required to form the sludge. If the developer is agitated, the sludge will cause trouble by settling out on the emulsions of plates, films, etc. Other salts have usually little effect on a developer, although chlorides and bromides exert a restraining action.

Dissolved salts often cause trouble by crystallising on the film after drying, and although not always visible as crystals to the eye, they detract from its transparency.

2. Suspended matter in the form of dirt and iron rust, which if not filtered or allowed to settle will cause spots.

3. Slime, consisting of animal or vegetable colloidal matter and which is not removed by filtering. If such water is used for mixing solutions, the colloidal matter gradually coagulates and settles out in the solution as a sludge.

4.—Dissolved gases such as air, sulphuretted hydrogen, etc. *Water dissolves about 2 per cent. of air at 70 deg. F. and when a developing agent like hydroquinone is dissolved without the addition of sulphite, the oxygen present in the water combines with the developing agent forming an oxidation product which will cause chemical fog.*

Sulphuretted hydrogen gas present in sulphur water will also cause bad chemical fog, but the gas may be removed by boiling or by precipitation with lead acetate.

Purification of Water.

Water may be purified as follows:

1. By distillation: Distilled water should be used whenever possible for mixing solutions.

2. By boiling: This coagulates the colloidal matter and changes certain lime salts to the insoluble condition which then settle out, while dissolved gases such as air, sulphuretted hydrogen, etc., are removed. Therefore, unless the water contains an excessive amount of dissolved salts it is usually sufficient to boil the water and allow it to settle.

3. By chemical treatment: If large quantities of water are required, chemical methods of purification must be employed, though it is only possible to remove lime salts, slime and colloidal matter in this way.

Excessive amounts of dissolved lime salts are very objectionable, because after washing if drops of water are allowed to remain on the plates or film, when the water evaporates the dissolved salts in the water become visible as a white scum.

The following methods of chemical purification may be adopted:

(a) Add alum to the water in the proportion of one gram to four liters. This coagulates the slime which carries down any suspended particles, and the solution rapidly clears.

This method does not remove dissolved salts, while the small amount of alum introduced into the water has no harmful effect on the developer.

(b) Add a solution of sodium oxalate until no further precipitate forms. This method removes the calcium and magnesium salts and coagulates the slime, though sodium and potassium salts are left in solution.

(c) Most of the commercial methods of water softening may be employed, though such methods do not remove sodium and potassium salts.

The "Decalso" process of water softening is one which can be recommended. The water is passed through a tank containing sodium aluminum silicate which is a Zeolite, and possesses the power of exchanging its sodium for the calcium and magnesium present in the water. When the Zeolite thus loaded with calcium and magnesium is washed in a strong solution of common salt (sodium chloride) it exchanges the calcium and magnesium again for sodium and is thus regenerated, and is in a condition for further softening. Full particulars may be obtained from the American Water Softening Company, 1,011, Chestnut Street, Philadelphia, Pa.

Impurities in Developing and Fixing Chemicals.

It is beyond the scope of the present article to indicate all the possible impurities which may be present in photographic chemicals. For a more detailed account the reader is referred to the paper by H. T. Clarke on "The Examination of Organic Developing Agents" (Phot. J. Amer., Nov., 1918, p. 481), which contains a number of analyses of developers recently placed on the market under fancy names and containing such substances as starch, sugar, salt, borax, etc.

In this article we are only concerned with the impurities usually present in chemicals which are not intentionally added as adulterants.

Impurities may have access to photographic chemicals in three ways: (a) during manufacture, (b) during storage, (c) during mixing and storage of the solution.

(a) If chemicals of repute are purchased, the photographer need not worry about impurities.

If the Elon, hydroquinone or pyro is coloured, the presence of fogging agents should be suspected, although some coloured samples do not give any more fog than colourless ones.

Many metallic compounds such as salts of copper and tin, metallic sulphides, etc., exert a powerful fogging action even when present only in minute quantities, and should be avoided. The following table indicates the nature and effect of the more common impurities present in the chemicals used for developing and fixing baths:

CHEMICAL. Pyro, hydroquinone, etc.	CHIEF IMPURITY. Oxidation products and adulterants	EFFECTS OF IMPURITIES. Chemical fog Adulterants weaken the effect of the developer Keeping properties of the developer are impaired Iron gives a dirty red solu- tion with pyro Decreases the accelerating power Diminishes the fixing power Diminishes the hardening action Excess of acid tends to cause sulphurization of the fixing bath Deficiency of acid causes milkyiness of the acid fix- ing bath due to the pre- cipitation of aluminium sulphite
Sodium sulphite	Sodium sulphate	
Sodium bisulphite	Iron and sodium sulphate	
Caustic soda	Sodium carbonate	
Hypo	Sodium sulphite	
Alum	Sodium sulphate and am- monium sulphate	
Chrome alum	Ammonium sulphate and Sulphuric acid	
Acetic acid	Water	

(b) For impurities introduced during storage see "Storage of Chemicals."

(c) If during mixing the water contains dissolved air and the developing agent is dissolved before the sulphite, it becomes oxidised, and the oxidation product formed causes fog. (See "Mixing of Developers," "Storage of Solutions," and article on "Chemical Fog.")

Storage of Chemicals.

Chemicals should be stored in well-corked or well-stoppered jars in a cool dry place, because most chemicals are affected by air which contains oxygen, carbon dioxide gas, and moisture.

(a) Oxygen readily attacks such substances as sodium sulphite, especially in the presence of moisture, converting it into sodium sulphate, which is useless as a preservative. With crystallised sodium sulphite the sodium sulphate form on the outside of the crystals as a powder, which may be washed off and the crystals dried. It is less easy to detect sodium sulphate in desiccated sulphite except by chemical tests.

Other substances which combine with oxygen and are therefore said to be oxidised are sodium bisulphite and potassium metabisulphite, and all developing agents such as pyro, hydroquinone, etc., which turn more or less brown, the extent of the colour roughly indicating the degree of oxidation.

(b) Carbon dioxide gas combines with substances like caustic soda and caustic potash, converting them into the corresponding carbonated alkalis which are less reactive. If caustic soda is kept in a stoppered bottle the stopper usually becomes cemented fast by the sodium carbonate formed, so that it should be kept in a waxed corked bottle. Owing to the solvent action of the caustic alkalis on glass the inside of the glass bottle containing caustic or strongly carbonated solutions becomes frosted, though the amount of glass thus dissolved away will usually do no harm.

(c) Certain chemicals have a strong attraction or affinity for the moisture present in the atmosphere, and gradually dissolve in the water thus absorbed forming a solution. This phenomenon is termed "deliquescence," and the chemicals are said to "deliquesce." Familiar examples are ammonium thiocyanate, potassium carbonate, caustic soda, caustic potash, sodium sulphide, uranium nitrate, sodium bichromate, etc., which should

be stored in corked bottles, and the neck dipped in melted paraffin wax.

As mentioned above, it is difficult to prepare a solution of definite percentage strength from a chemical which has deliquesced, though it is usually sufficient to drain off the crystals, or to use a hydrometer, referring to a table giving the hydrometer readings in terms of percentage strength.

(d) While some chemicals absorb moisture as above, others give up their water of crystallisation to the atmosphere, and therefore lose their crystalline shape and fall to a powder, and are then said to "effloresce," the phenomenon being termed "efflorescence." Some crystals do not contain any water, and therefore cannot effloresce.

A very dry atmosphere is suitable therefore for storing deliquescent salts, but not for efflorescent salts. The only way to store chemicals is to isolate them from the air by suitably sealing.

How to Store Solutions.

Stock solutions and developers should be stored in either large glass bottles, earthenware crocks, wooden vats, or tanks of resistive material, and so arranged that the liquid may be drawn off at the side and near the bottom.

Large glass bottles and crocks should be fitted with a right-angled glass or lead tube passing through a rubber stopper wired to the bottle, the tube being opened and closed by means of a punch cock clamping a short length of rubber tubing.

In case a solution such as pyro has to be stored for a long time and withdrawn at intervals, an absorption bottle containing alkaline pyro may be fitted at the intake, which absorbs oxygen from the air as it enters the bottle after withdrawing part of the solution.

It is often recommended to pour a layer of refined mineral oil on the surface of a solution so as to protect it from the air, though this is very messy when the bottle has to be refilled.

A battery of stock solution bottles is shown in Fig. 3, the bottles being arranged on lead-covered shelves under which a large trough is placed, or, the floor may be so arranged as to form a sink, so that in case of accidental breakage no serious damage is done. This precaution is of special importance in the case of hypo solutions which might otherwise flood an entire building and inoculate the various rooms with hypo dust causing an epidemic of spots. J. I. CHARTREE.

THE PHOTOGRAPHIC CORRECTION OF NEGATIVES TAKEN OBLIQUELY.

[For the purposes of the French Army Aviation Service, in which he was engaged during the greater part of the war, M. L. P. Clerc has investigated with great thoroughness the mathematical conditions involved in transforming a photograph taken from an inclined aerial camera into one corresponding with that obtained from the same view-point, but with the lens axis vertical. His study has led him to the design of a purely automatic camera carrying out this "redressement." Inasmuch as aerial photographic mapping promises to be an important peace-time application of photography we publish a translation of the text of his paper.—EDS. "B.J."]

(Continued from page 399.)

If we draw in the plane T a series of parallels to the direction a, b (one of the systems of parallels forming the squaring of the map, for example) these straight lines will have their vanishing point in D on the negative H A D. In the image projected by the lens O on the plane H' A' D', the images of these straight lines will be directed all towards the point D' at infinity and will thus be parallel to each other. Every series of parallels in the plane T will thus be represented in the new projection by a series of parallels.

This having been done, consider in the plane T two equal segments a, b , and c, d , on the same straight line (fig. 7) and in this same plane a segment x, y , equal and parallel to the two others. The two parallelograms a, b, x, y , and c, d, x, y , will be represented, in the plane P' M of the new projection, by two parallelograms A' B' X' Y'

and C' D' X' Y', and, therefore, equal segments taken on the same straight line of the plane T will have as images, in the corrected projection, equal segments on a straight line.

Consider now (fig. 8) a squared pattern in the plane T such that one of its directions p, r coincides with the intersection of the plane T by the vertical plane containing the axis of the taking lens. The two directions of this squaring then have, as images in the plane P H D of the negative, directions which are respectively those of the line of greatest inclination (V H) of the plate and of the horizon line H D. The image of this squaring in the plane of the corrected image will be defined by the angles made with P' V' (image of p, r) by the direction P' Q' of the other system of parallels and the direction P' R' the image of p, r , the diagonal of the squaring.

Calling the angle $v' p, r$, σ and the corresponding angle V' P' R',

Σ' , we apply the relation [1] above to determine the directions of $P'Q'$ and $P'R'$ relatively to $P'V'$ —

$$v' p_1 q = \frac{\pi}{2} \quad \tan v' p_1 q = \infty \quad \tan V' P' Q' = \frac{SH}{OH} \quad \tan v' p_1 q = \infty$$

$$v' p_1 v = \sigma \quad V' P' R' = \Sigma' \quad \tan \Sigma' = \frac{SH}{OH} \tan \sigma$$

It will thus be seen that the particular system of squares considered in the plane T has, as its image in the corrected projec-

Fig. 7.

tion, a system of rectangles. In order that the corrected image of the squared pattern shall itself be a system of squares, it is necessary that

$$SH = OH \quad [2]$$

—that is to say that the distance of the horizon line from the optical centre O of the lens used for correction shall be equal to

Fig. 8.

the distance of this same horizon line from the optical centre S of the taking-lens.

In all other cases the corrected figure will be a homographic deformed rendering of the squaring projected on the plane of the map, the image being extended or compressed * in the direction of the lines of greater inclination of the negative.

If we take $k = \frac{SH}{OH}$, the image will be, in the direction of the lines of greater inclination, extended if $k > 1$, or compressed if $k < 1$.

§6. Condition of Correction without Deformation.—Since any figure can always be formed from a squared pattern of infinitely small squares, it will be seen that the corrected figure will be similar to the figure drawn on to the plane of the map if the above condition [2] is observed.

The horizon line being usually not included in the field of the photographic plate, which it is proposed to correct to a horizontal rendering, it is useful to express the condition of complete correction in a form capable of more direct application.

From the right-handed triangles, SPH and OFH,

$$SH = \frac{SP}{\cos HSP} = \frac{F}{\sin \omega} \quad OH = \frac{OF}{\cos FOH} = \frac{f}{\sin \beta}$$

* The term *single conversion transformation affine* is sometimes applied to a deformation of an image in which there is enlargement or compression in one direction without alteration in the direction at right angles. In the case where the condition (3) mentioned above is not fulfilled the corrected image represents such single conversion of the projection of the terrestrial region in the plane of the map. Single conversion can be produced only by parallel projection in which the plane of the picture is not parallel to the plane of the original figure, or, as in the present instance, by means of two conical projections. The intermediate image in this case is common to the two projection systems, as is also the corresponding counter axis (the horizon line in the present instance).

The condition [2] is thus written:

$$\sin \beta = m \sin \omega, \quad [C]$$

taking, as before, $f = mF$.

7. The condition [2] worked out in the preceding paragraph can also be established directly from the properties of conical projections and homographic transformations. It can be shown that the locus of the centres of projection O, permitting of projecting from a photographic negative an image similar to that which would have been obtained from the same view-point on a horizontal plate is a circumference, described from the point H as centre, in a plane perpendicular to the horizon line and passing through the nodal point of emergence S of the taking lens. To each point O of this circle there corresponds a single direction of the plane of projection—namely, that of the plane passing through O and the horizon line of the negative (Fig. 9). From this property a graphical construction of the various elements of the system of projection which results in correction may be worked out.

The horizon line being in the focal plane of the lens O, we draw with H as centre a circle of radius equal to the focal length f.

Fig. 9.

From the point O selected draw the two tangents to this circle, which cut respectively the intersection of the plane of the negative in M_1 and M_2 . Through the straight lines, perpendicular to the plane of the figure and containing these points, draw planes parallel to the plane determined by O and the horizon line H. The intersections of these planes are their intersections M_1P_1 and M_2P_2 , in the plane of the figure. Through O draw the perpendiculars Oz_1 and Oz_2 to the planes OM_1 and OM_2 . In this way are defined two positions of the optical axis of the lens O serving for the required correction. The position of this axis in respect to Oz_2 permits the projection of a real corrected image on the plane M_1P_1 . The position of the same axis in respect to Oz_1 would give in the plane P_2M_2 an image which is virtual, and thus of no importance. Moreover, on the graphical construction the lengths of the segments intercepted on the optical axis, in one direction or the other from the centre, by the plane of the negative, and the plane of the image may be determined, as well as the angles α and β and the extent d of the decentering.

It will be seen that the choice of the point O on the circle of radius, HS, being purely arbitrary, the problem allows of an infinite number of solutions which thus permits a further condition being imposed, for example, the scale of the corrected photograph.

Suppose, for example, we reproduce with enlargement nP the principal horizontal of the negative the intersection of which is in P, the plane of the corrected image being parallel to the plane of which the intersection is HO. Since the triangles are similar it is sufficient to determine, on the intersection PH of the negative and of the plane of the figure, a point M_1 such that:—

$$\frac{HM_1}{HP} = \frac{OP_1}{OP} = nP$$

The position of M_1 being once fixed, we draw from this point a tangent to the circle of centre H and radius f. In general, this

tangent will cut the concentric circle of radius HS at two points, O and O', satisfying the fixed condition. The position O' of the optical centre of the correcting lens would, however, correspond to the reproduction of the negative at an obliquity such that the operation would be practically impossible.

§8. *Calculation of the Scale of the Corrected Image.*—We will now proceed to discover on what scale n_P the terrestrial area has been photographed on the principal horizontal of the negative, and will then determine the scale n_P for this horizontal at the time of correction. The product N of these two ratios represents the scale of the corrected image.

The scale on the principal horizontal of the negative (fig. 1), calling H the altitude of the view-point S, is

$$NP = \frac{SP}{S_{P_1}} = \frac{F}{S_{P_1}} = \frac{F \cos \omega}{H}$$

In order to determine the enlargement n_P we have given the similar triangles POH and PMP' (fig. 5)

$$n_P = \frac{P'O}{P'O} = \frac{HM}{PH} = \frac{f \sin \alpha}{F} = \frac{f \tan \omega}{F \sin \alpha}$$

and therefore

$$N = N_P n_P = \frac{f \sin \omega}{H \sin \alpha}$$

which may be written

$$\sin \alpha = \frac{f}{NH} \sin \omega \quad [1]$$

noting that the denominator NH represents the altitude of the view-point reduced to the scale of the corrected image or the equivalent focal length of the corrected photograph.

9. *Correction in Practice.*—Correction is preferably done with a camera such as is used for the copying of transparencies, the negative carrier and the plate-holder being mounted upon a rocking frame pivotted on axes perpendicular to the axis of the lens, the two axes of the rocking frames being parallel.

The negative to be corrected requires to be placed in the carrier so that one of its horizontals is parallel to the intersection of the planes of the negative and of the corrected image, that is to say, parallel to the axes of the rocking frame.

The direction of the horizontals in the negative and the angle of taking ω are supplied either by appropriate clinometers, mounted on the taking camera or even, in the case of a well-known region which presents numerous datum points, by graphic construction.

The conditions which have been worked out in preceding paragraphs and which are as follows:

- (A) $\tan \beta = n \tan \alpha$
- (B) $d = F \frac{\cos \beta - \cos \alpha \cos \omega}{\sin \omega}$
- (C) $\sin \beta = m \sin \omega$
- (D) $\sin \alpha = \frac{f}{NH} \sin \omega$

permit of determining successively β (condition C) in terms of m and of ω which are known: also α (condition D) in terms of f , which is known and of NH which is suitably chosen. We can also determine the amount d of decentering (condition B) in terms of the focal length F of the taking camera and of the angles α , β and ω , and lastly, the enlargement n on the optical axis (condition A) in terms of the angles α and β , the known value of this enlargement permitting of fixing the lengths of the segments OA and OA' limited, on the optical axis respectively to the centre O by the planes of the negative and of the corrected image.

It will frequently be better to substitute for the measure of decentering d , as defined in paragraph 4, the measure of the movement $e = AP$ (fig. 5) to be given to the negative, in its plane in order to bring the principal horizontal to the distance suitable to the horizontal of the negative meeting the optical axis. The extent of this movement is

$$e = AP = \frac{d}{\cos \alpha}$$

and should be reckoned positively from the optical axis towards the intersection M of the two planes.

§ 10. *Possible Conditions.*—The geometrical conditions of possibility of correction are shown by the condition that the values found for $\sin \alpha$ and $\sin \beta$ (conditions C and D) are less than 1, viz.,

$$\sin \omega < \frac{1}{m} \quad \text{and} \quad NH > m F \sin \omega$$

The optical considerations limit the angles α and β to values greatly less than the limiting value of 90° obtained on purely geometrical grounds. In practice, angles of 30° should never be exceeded both for the negative and the plane receiving the corrected image.

The possible conditions thus become

$$m \sin \omega \leq 0.5 \quad \frac{f}{NH} \sin \omega \leq 0.5$$

$$\sin \omega \leq \frac{1}{2m} \quad NH \geq 2m F \sin \omega$$

It will thus be seen that the correction will be possible for values of the angle ω greater in proportion as the ratio m of focal distances (of correction and taking) is small; that is, as f is small, and, on the other hand, in the case of a negative taken under a given angle, the corrected image can be brought—without limitation of maximum scale—to a scale small in proportion to m .

From all these considerations it is advisable to select for the correcting camera a lens of the minimum focal length compatible with sufficient covering power and freedom from distortion over the required field and with the necessary provision for decentering.

11. *Cartographic Use of the Corrected Negatives.*—It must be noted in the first place that the corrected photograph is not identical with the map, but is only similar to the conical projection of the terrestrial region made from the centre S on to a horizontal plate T (fig. 10).

In the image taken obliquely and corrected without deformation the property of the central principal point P no longer applies to

Fig. 10.

the image P' of P, but, in the case of correction on a horizontal plate, to the image V' of the vanishing point of the verticals, and, in the case of correction on a vertical plate, to the image H' of the principal horizon point H.

L. P. CLERC.

(To be continued.)

DEMONSTRATIONS OF THE CARBON PROCESS.—Secretaries of photographic societies who may wish to include a demonstration of carbon printing in their syllabus, should note that the Autotype Company offer them facilities for doing so. The Company does not send out lecturers, but is ready to supply all necessary materials for a demonstration, sending exposed carbon tissues ready for development together with transfer papers and such literature as will enable anyone having even a short experience in the process to give a demonstration. The arrangements, in fact, admit of members of a club entering into a species of competition in carrying out the instructions sent by the Autotype Company. Application should be made to the Company at 74, New Oxford Street, London, W.C.1.

A COPYRIGHT INFRINGEMENT CASE.

KEOGH BROS., LTD., v. LEVENTHAL.

JUDGMENT has recently been given in the Chancery Division of the High Court of Justice, Ireland, by Mr. Justice Powell in a case of infringement of copyright which, while not providing any fresh interpretation of copyright law as modified by the 1911 Copyright Act, possesses some interesting features. The following is an abridged summary of the proceedings, abridged that is from the citation of them contained in the judgment of Mr. Justice Powell. We reproduce verbatim only that portion of the judgment which deals specifically with the application of the 1911 Act to the circumstances of the case.

The defendant firm had published a postcard entitled "Easter, 1916," and also a large photogravure of the same subject in which was depicted a group of fourteen members of the Irish rebellion seated round a table. Certain figures in the group appeared to be copied from photographs of the persons taken by the plaintiff, but the defendant denied that this was so, and stated that he bought an oil painting from an artist named Rogers, and that this painting was an original work from which he reproduced the photogravure and the postcard.

The plaintiff firm had made certain group photographs in circumstances which entitled it to the copyright in them, and had produced for publication and sale certain cabinet photographs made from single figures in these groups and representing Michael O'Hanrahan, Thomas J. Clarke, and Cornelius Colbert. There had been a considerable sale of these enlarged photographs, and the photographs had been reproduced in Irish and English newspapers, and reproduction fees had been paid to the plaintiff firm. The plaintiff showed that the three single enlarged cabinet photographs of O'Hanrahan, Clarke, and Colbert were identical with the three photographs of these men in the photogravure and postcards issued by the defendants. There were slight differences such as could have been made in reproduction, but the faces were identical.

The defendant stated that the reproductions were made from an oil painting in black and white made for him by an artist named Rogers, and that he was not aware of the methods adopted by Rogers or of any copyright in any of the portraits. Under cross-examination, he said that if he knew they were from photographs he would have asked about them. He said he knew they were from something. He made no inquiry.

Mr. W. J. Rogers, the artist who had produced the infringing work, said that in 1917 he conceived the idea of producing and composing an original sketch of leaders of the rebellion done in pencil; that he did not get any of the three sketches from the plaintiff's photographs; that he saw them in the Press; that he had no photographs beforehand; that he transferred them to the cardboard of the oil painting, and then painted them in in black and white in oils, afterwards taking them to the defendant with whom he made a contract. Under cross-examination, he admitted that he had seen Colbert's portrait with the plaintiff's name on it in the "Irish Times," that he had seen Clarke's photograph in the "Irish Times," but did not notice plaintiff's name to it, and that the only photograph he had seen of O'Hanrahan had been in the "Irish Times."

The defendant, recalled by the Judge, stated that the photogravures were first sold on May 8, 1918, and that he learned that the sale of these pictures was prohibited at the end of September, 1918, and he ceased selling after that date.

Plaintiff, recalled by his counsel, stated that he had been publishing the cabinet photographs from 1917 down to the time of the hearing in the public Press.

It was submitted by counsel for the defence that Mr. Rogers was able from memory to produce these sketches of the persons represented, but even if that explanation were not accepted, it was contended that the photogravures were not an infringement even if taken from the plaintiff's photograph. It was argued that the object of the 1911 Act was the same as that of the 1862 Act, namely, to protect the owners of the copyright in their reputation. Counsel referred to the case of Hanfstaengl v. Baines (1895) and Hanfstaengl v. Empire Theatres. He said that the reproductions, even if copies of the three enlarged photographs, could not be said to be injurious to the plaintiff. The reproduction was a group; it did not compete with the photographs of the plain-

tiff. It had no effect on the artist's reputation, nor on its commercial value, and he referred to the fact that the sale of the photogravure and the postcards had been forbidden under the Defence of the Realm Act. It was argued that the Court should not restrain the defendant from selling when, in fact, there had not been a sale; there was no evidence of a future intention to sell, and that therefore no injunction should be granted. Counsel stated that the plaintiff had expressed their intention to circulate the same group, and that there was no evidence of damage.

Counsel for the plaintiff contended that even if the production had been brought about by memorising, this would be an infringement, and he strongly relied upon the similarity between the portraits in the postcards and in the photogravure and those in the cabinet photographs, pointing out that even two negatives taken on different occasions could not produce such a likeness.

Mr. Justice Powell, in the course of further reviewing the evidence said he could not bring himself to accept the story of Mr. Rogers. He did not believe it would be possible for him by means of the process which he detailed to procure a production in the postcard or in the photogravure of photographs practically identical with the cabinet photographs in question. He had come to the conclusion that the group was arranged by the defendant and Rogers together and pointed out that the defendant had not contradicted this evidence, but had stated that he did not remember making the statement to a representative of plaintiff's solicitor to the effect that he and Rogers had arranged the group. On this interpretation of the evidence presented to the Court, the judgment of Mr. Justice Powell in respect to the application of the Act to the circumstances of the case, was as follows:—

Under Sect. 1 (1) of the Copyright Act, 1911, copyright subsists in every original literary, dramatic, musical, and artistic work, and by the definition clause [Sec. 35 (1)] "Artistic Work" includes photographs.

By Sect. 21 the term for which copyright shall subsist in photographs shall be fifty years from the making of the original negative from which the photograph was directly or indirectly derived, and the person who was owner of such negative at the time when such negative was made is to be deemed to be the author of the work. By Sect. 1 (2) for the purposes of the Act copyright means the sole right to produce or reproduce the work or any substantial part thereof in any material form whatever. By Sect. 2 (1) copyright in a work, that is, copyright in a photograph (*inter alia*) shall be deemed to be infringed by any person, who, without the consent of the owner of the copyright, does anything, the sole right to do which is by this Act conferred on the owner of the copyright. In this case the defendant has reproduced, as I hold, the three cabinet photographs, placed them in the group in the postcard and photogravures, and offered for sale and sold them. By Sect. 2 (2) copyright shall also be deemed to be infringed by any person who sells or by way of trade exposes or offers for sale or hire, or distributes either for the purpose of trade or to such an extent as to affect prejudicially the owner of the copyright, or by way of trade exhibits in public any work which to his knowledge infringes the copyright, or would infringe the copyright if it had been made within the part of H.M. Dominions, in or into which the sale, exposure, offering for sale or hire, distribution, exhibition, or importation took place. Sect. 5 (1) provides that, subject to the provisions of the Act, the author of a work shall be the first owner of the copyright therein, provided that where, in the case of an engraving, photograph, or portrait, the plate or other original was ordered by some other person, and was made for valuable consideration in pursuance of that order, then, in the absence of any agreement to the contrary, the person by whom such plate or other original was so ordered should be the first owner of the copyright. In this case neither the plate nor original was ordered by any other person.

It is suggested on behalf of the defendant that he is not liable because he was not aware that the plaintiffs had any copyright in these photographs, relying, I take it, on Sect. 2 (2) of the Act of 1911; but this section and sub-section must be read together with Sect. 2 (1). Here the plaintiffs allege that the defendant himself, although warned by the plaintiffs, persisted in doing several acts the sole right to do which is by the Act conferred on the plaintiffs as the owners of the copyright. He has reproduced these photographs in his picture postcard and in his photogravure, and the meaning

of Sect. 2 (2) is that not only the person who reproduces a copyright work is liable to an action, but persons who deal with infringing copies may also be liable, the latter, however, only if they do so knowingly. I, therefore, do not think that Sect. 2 (2) applies in this case as to confine the plaintiffs to the remedy by way of injunction only provided by Sect. 8, but if it were necessary I am quite prepared to hold, on the evidence, that the defendant knew that the plaintiffs had a copyright in these photographs, and that he was infringing the copyright because rejecting, as I do, the version of Rogers and himself as to the alleged history of the picture postcards and the photogravure, and believing, as I do, that, as regards the three men in question, their photographs (cabinet) were reproduced from the plaintiff's photographic groups, it is, in my view, impossible that the defendant could not but be aware that these photographs of the groups were the property of the plaintiff, seeing that the name and address of the plaintiff is stamped upon the three photographs of the groups from which, as I hold, the reproductions were taken.

On this point I have been referred by counsel for the plaintiffs to the case of *Byrne v. the "Statist" Co.* (1914, K.B. 622), and to the judgment of Bailhache J. in that case ("B.J.," Jan. 30, 1914, p. 91.—Eds.). There, as the judge points out, the advertisement contained upon its face an intimation that it was translated by the plaintiff, and the defendant's witnesses had stated that they attached no importance to this, and the judge held that they were wrong, and found, as a fact, that there was reasonable ground for suspecting that there was copyright in the plaintiff's translation.

Mr. Browne put forward an alternative defence, contending that the oil-painting and photogravures and picture postcard were not an infringement of the plaintiff's copyright, even if taken from the plaintiff's photographs, the object of the Acts of 1862 and 1911 being to protect owners of copyright in their reputation, and that the group photographed in the picture postcard and in the photogravure, and painted in the oil-painting, even if copied as regards the three men in question from the plaintiff's photographs, was not the infliction of an injury upon the plaintiff's; he says that these productions of the defendant constitute entirely different work, but as regards the latter point, it was held by Romer J. on "*Brooks v. Religious Tract Society*" (65 W.R., 476) that where one found a direct copy of a substantial portion of a copyright work, that substantial portion constitutes an infringement if it was a copy in an ordinary sense. On the point as to whether the infringement here was an injury to the plaintiffs, Mr. Browne relied upon the judgment in the case of "*Hanstaeagl v. Baines*," and the observations in the judgment by Lord MacNaghton at p. 29 to the effect that if the object of the Act of 1862 be, as he supposed it was, to protect the reputation of artists and preserve intact the commercial value of artists' work, it appeared to him that the sketches in the *Daily Graphic*, of which the complaint was made, were not within the mischief which the Act was designed to repress. There could not, he thought, be any possibility of any injurious effect on the artist's reputation, nor could the reproduction in any conceivable circumstances detract from the commercial value of the artist's work or come into competition with it or any reproduction of it. It is quite enough, as it seemed to him, to place the sketches in question alongside any photograph of the pictures of which they were alleged to be piratical copies. In that case the appellant was the owner of a copyright according to German law in certain pictures painted in Germany. At the theatre of the Empire Palace, in London, representations were given of those pictures, and sketches of the pictures were published by the respondents in the *Daily Graphic* newspaper with explanatory letterpress. The appellant brought an action against the Empire Palace, Limited, and the respondents to restrain them from infringing his copyright by their respective representation, and for damages, and it was held by the Court of Appeal, affirming Sterling J., that the living pictures were not an infringement of the copyright. Upon the motion for an injunction against the respondents in the case under review, Sterling J. granted an interim injunction, and the order was discharged by the Court of Appeal, and from this decision the plaintiff appealed. Lord Herschell pointed out in that case that it was not accurate to say that the living pictures were copies of the paintings. It is admitted, he says, that the faces at all events are different. It is not shown, he says, that the countenances of the living persons who figured upon the stage bore any close resemblance to those depicted

by the artist. In some cases, he says, this difference would be all-important. Lord MacNaghton apparently adopts this statement of Lord Herschell, as appears by what he says that to place the sketches in question alongside any photograph of the pictures of which they were alleged piratical copies would convince anyone that they could not come into competition with the picture or any reproduction of it. But I do not think that this applies in the case before me, because, save for wholly immaterial differences, the photographs of the three men in question in the defendant's productions are, as to their faces, really reproductions of the photographs of these men taken by the plaintiffs.

I am therefore of opinion that the plaintiff is entitled on the whole case to an injunction restraining the defendant, his servants and agents, from making, publishing, selling or offering for sale, any copies, reproductions, or imitations of the plaintiff's photographs of these three men, or any of them, or otherwise infringing the plaintiff's copyright therein, and to an account and delivery up of all paintings, copies, and imitations of these photographs, together with all blocks, plates, and other devices used or intended to be used for the production of such infringing copies, reproductions, or imitations in the possession, custody, or control of the defendant, his servants, or agents.

I do not think it necessary to declare the plaintiffs entitled to an account of profits. As regards damages, I have no materials before me for assessing more than nominal damages. On this point, Counsel for the plaintiffs have referred me to the statement in Mr. Coppinger's work at p. 199 that the measure of damages under S. 6 (1) will be the loss which the proprietor of the copyright has suffered by reason of the diminution of the sales of his work, or the loss of profit which he might otherwise have made. The fact that pirated work may have injured the reputation and vulgarised the original is also a fact that may be taken into consideration in assessing the amount of damages, and the case of "*Hanstaeagl v. Smith*" (1905, Ch. 519) is referred to. In that case, on the question of damages, Mr. Justice Kekewich says that he was struck by the view supported by the plaintiff's witnesses that such a publication as appeared in the magazine referred to vulgarised that of which it is a reproduction—that is, tends directly to prevent the sale of the plaintiff's goods by reason of the familiarity of the public with the base form. Notwithstanding that fact, he declared the plaintiff entitled to a verdict in nominal damages only.

I am not prepared to hold that the inclusion of these three men in a group amongst other men whose photographs appear in the three productions complained of vulgarises that of which it is a reproduction. The sale of these productions of the defendant has been, in fact, suppressed, and was suppressed at an early stage. No doubt it is stated in Mr. Coppinger's work at p. 199 that the damages may be said to be at large, but that does not mean that I am to make an arbitrary award of damages. I will award the plaintiffs the sum of £1 for damages, and, of course, the defendant must pay the costs.

A BOOK OF THE CINEMA.—Messrs. Harper and Brothers, New York, have just issued a large and well-illustrated book on the making of motion pictures, largely historical, but dealing in a popular way with the making of film pictures of all kinds. The author is Mr. Homer Gray.

THE PHOTOGRAPHIC CONVENTION AT OXFORD.—After the suspension of its meetings since 1914, the Photographic Convention met last week at Oxford, under the presidency of Mr. G. W. Atkins. It is eighteen years since a previous meeting of the Convention was held at Oxford, and in an address of welcome to the members, Mr. G. W. Norton referred to the changes in its membership which so long an interval of time had brought about. On the evening of Thursday last week, July 10, Sir Cecil Hertelet delivered a most interesting lecture on his experiences at Antwerp as Consul-General for Belgium during the invasion of the country in August, 1914. Excursions were held during the week, on the Wednesday, by river launch to Abingdon and Sutton Courtney, and on Friday last to the Vale of the White Horse. The annual dinner was held at the Clarendon Hotel, and was followed by an excellent musical programme of Mr. J. Gilbert Wilbin.

Photo-Mechanical Notes.

Progress in Rotary Gravure.

Mr. C. W. SAALBURG, who has taken out many patents for improvements in rotary photogravure, the novelty of some of which we have ventured to dispute, has been granted a United States patent, No. 1,290,786, for printing a grain on carbon tissue and superposing this over the tissue containing the usual screened image. He claims this avoids "devils," and has other advantages.

From the peculiar appearance of the shadows in most machine-printed photogravures, it was often supposed, in the early days, that there was a supplementary grain applied to the plate somehow; but since the process has become less secret it has been found that the effect is simply due to the specific character of the ink used and the way it dried on the paper where it was thickest—that is, in the shadows.

It has often been remarked that three and four colour work in rotary photogravure looks flat: sparkling oil paintings reproduce as though the originals were pastel drawings. Attempts have been made to overcome this by printing on to glazed or gelatinised paper. Silks and mercerised cotton should provide a glossy surface that would overcome this defect, and printing on these materials should also have the advantage that a little want of register, which is very difficult to avoid entirely in rotary photogravure, would escape notice.

Before the war many experiments were being made in applying this process to the printing of wall-paper and textiles; of course, they were kept closely secret, and presumably have been dropped during the war. No doubt they will now be resumed, and great progress is certain along these lines sooner or later.

Hints on Metal Printing.

THE copper offered the engraver is often none too well buffed and polished. Sometimes scratches are quite obvious, and in this case there is nothing for it but plenty of elbow grease, first using fine pumice powder and afterwards charcoal, until all the scratches are removed. But sometimes the surface appears free from scratches which, however, appear after the etching is done. Apparently in manufacture the copper sheets have been ground with a coarse grit, and some of the deeper scratches have not been afterwards polished away, but have been merely hurred over. In this case the only thing that may help at all, if such a condition is suspected with any given lot that cannot be exchanged, is to use a negative that will stand a heavy printing and an enamel solution that is thicker than usual. To make printing on metal as uniform as possible, all conditions should be kept as uniform as possible, for example, the enamel solution should not only be made up to the same formula, but should be tested with a hydrometer, and always used at a definite strength or, rather, viscosity. Then if the whirling is uniform and the light the same, and kept at the same distance from the frame, the exposure will be the same and development also. A good average figure is 10 deg. Baumé, but this may be much lower if conditions will permit of a thinner solution, and this is advantageous as it shortens the time of printing considerably. There is no need to waste any of the enamel solution that drains off the plate; even the first coating which carries away the water may be saved and made up to hydrometer strength with the addition of some thicker solution. Filtered, it is just as good as fresh solution. Enamel is much more liable to come off zinc and brass than it is off copper. Too copious rinsing with water seems to be the most potent cause of loosening the enamel film.

Film in Photo-Mechanical Work.

IN the United States film is being increasingly used in black and white work, particularly in rotary photogravure. Films of several degrees of contrast are available. In large sizes they are cheaper than dry-plates, and they do not suffer from the disadvantage of the occasional waviness which characterises the glass of the average dry-plate, but the chief reason for their preference is that they can so easily be cut up and fitted together in any position required to make the large newspaper page, so popular in the Sunday supplements in rotary photogravure which every important newspaper in the United States now runs.

There are not, however, so far, on the market any holders for

large-size film, and various devices are used by the operators to hold these films in the dark-slide. One is to place the film on a piece of plate-glass and back it up with another piece of glass. This is open to the objection that any dust or defect in the glass is reproduced in the negative, and the focus must be altered to allow for the film not being in the usual focal plane.

Another method is to use a piece of thin, flat board—stout card-board does, and pin the film on this with drawing pins, then handle just like a dry-plate. Still another method is to lay the film on a piece of glass and stick down the top edge with adhesive tape, such as surgeons use. See that the film is perfectly flat; then stick the bottom edge in the same way, and the slides, too, if there is any sign of curl. Both of the latter methods seem quite satisfactory.—A. J. N.

A Problem in Half-tone Photo-Lithography.

ONE of the drawbacks in connection with photo-lithography, particularly in colours, is that it is next to impossible to do any retouching or correcting on the printing surface, and even if it were possible it would be impracticable for those step-and-repeat processes in which the original negative, and not a transfer, is used to make every repeat. So the retouching must be done on the negative, and if continuous-tone negatives are made, this is not so difficult, as is obvious in the beautiful collotype reproductions in colour, such as the Medici prints, which must have considerable retouching, all done on the negative before the collotype plate is made. But the lithographer who wants a grained negative does not want to use the indirect process if it can be avoided, yet if he makes cross-line screen negatives direct, he finds them difficult to retouch—practically impossible. So usually a continuous-tone negative is made on a plate the glass side of which is ground so that it will take pencil readily on the back as well as on the film. A positive is made from this which can be still further retouched and the screen negative made from this, when (if the work has been properly done) no retouching could be required on the plate.

W. C. Huebner, one of the inventors of the Huebner-Bleistel step-and-repeat machine for photo-lithography, has recently obtained a U.S. patent, No. 1300729, for a somewhat different method. He apparently dislikes the cross-line screen; at all events he sets forth in his specification several disadvantages, and appears to imagine you can get a greater range of tone with an irregular grain. As in either case you are limited by the black of the solid printing ink at one end and the white the colour of the paper of which you have to print at the other, it is difficult to see how you can get a longer range of tone with one method than with the other. However, apart from his reasons, his method is certainly ingenious for he takes an ordinary continuous-tone negative or positive, retouches this in the usual manner, and then prints from it on to bichromated gelatine solution spread upon glass, which solution contains calcium chloride or other substance to cause it to give a grained effect; in other words, he produces a grained collotype plate. He now inks this up or treats it with opaque powder, and then uses it as his negative to print on his plate, and thus obtains his grained photo-lithographic printing surface.

Ceramic Half-Tone Screens.

A PROCESS for the making of half-tone screens which has been protected by patent is described in specification No. 124,608 by Mr. E. W. Smith, of 69, Alexandra Road, Hornsey, London, N.8.

Mr. Smith draws or engraves on a lithographic stone, zinc block or plate, a fine granular stipple or other configuration and after rolling (or inking up) through the medium of an india rubber covered roller, he transfers the design on the stone or plate to a sheet of glass. The glass may be held on a moving or fixed bed-plate of a machine and the roller positioned in a frame so that on the movement of the bed-plate or the roller the design can be transferred from the roller to the glass with great exactitude, the roller being adjusted so that the necessary pressure is imparted to effect a sharp and clear imprint.

In rolling or inking up the stone, plate or block having the design thereon when it is required to be permanent a suitable varnish is used for the purpose such as that known as printers' varnish. The design (or configuration) is transferred to the glass as described.

and dusted with an opaque glass enamel or glaze powder or the like and afterwards fired in a muffle or kiln.

The design on the stone or plate can be inked up sufficiently sparsely so that it is not blurred when transferred from the printing cylinder to the glass and when dusted with the enamel powder and fired in the muffle or kiln the full depth or density of the design is obtained sharp and clear.

When it is not required that the design or configuration be permanent, instead of dusting with the enamel powder and firing in a muffle or kiln use may be made (after transferring the design to the glass as described) of any dusting powder and the firing omitted in obtaining the desired result.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, June 30 to July 5.

PRINTING FRAMES.—No. 16,498. Spring arrangement for printing frames. J. F. Hansen.

PROJECTION SCREENS.—No. 16,424. Moving picture display screen. Eureka Screen Co. and W. J. Mellersh.

CINEMATOGRAPHY.—No. 16,714. Apparatus for taking and displaying moving pictures. A. Barnett and E. Esdail.

CINEMATOGRAPHY.—No. 16,735. Cinematograph apparatus. Barr and Stroud and J. W. French.

CINEMATOGRAPHY.—No. 16,601. Cinematograph apparatus. W. R. Campbell.

CINEMATOGRAPHY.—No. 16,467. Means for recording and reproducing sound and for synchronising the same for cinematograph purposes. F. H. Fountain.

CINEMATOGRAPHY.—No. 16,891. Automatic safety control for cinematograph machines. R. M. Geyer.

CINEMATOGRAPHY.—No. 16,546. Automatic safety shutters for cinematograph apparatus. A. H. Marshall.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

FOCUSsing FINDERS.—No. 116,095 (May 16, 1917). The invention refers particularly to the type of focussing finders for photographic cameras which comprise a focussing lens with substantially the same focal length as the lens of the camera, a bellows to

Fig. 1.

the outer end of which the lens is attached, a focussing screen, and a reflecting mirror hinged to the screen. The invention consists principally in this that the bellows, the mirror, and the screen are so connected with one another that they may be folded into a position parallel with one another.

In the drawings, 1 is a rectangular frame provided at its upper

four edges with hinges connecting plates 25 and 26, which serve as a guard against outside light on the image recording focussing screen 2, mounted in the upper part of the frame. In order to secure the light guard in its upright position, and at the same time to prevent the entrance of light at the corners between the different plates, the plates are provided on each upright edge with a flange or bend, and hinges so that the plates will press against the upright edges of the plates. The plate carrying the mirror is connected by means of hinges to the frame. To this plate side plates 7 are connected by means of hinges, and the plate 9 by means of hinges 8.

Devices employed in the present instance for adjusting the lens consist of corresponding threads in the lens holder and on the

Fig. 2.

lens mounting, hence by turning the lens it may be moved in the direction of its axis.

The focussing finder is to be adjusted when attached to the camera, the adjustment being effected by focussing the camera by means of its focussing scale on an object whose distance from the camera is known, or on so-called infinite distance, whereupon the lens of the focussing finder is to be moved to and fro by the means above described until the image on the focussing screen is sharp. This having been done for one certain distance, the image will also appear sharp for any other distance, as the focal length of the lens of the focussing finder is the same as that of the lens of the camera. Georg Samuel Lalin, 7, Ryttagatan, Raasunda, Sweden.

X-RAY PAPER.—No. 125,490 (Sept. 18, 1918). The invention consists in providing a photographic emulsion capable of being successfully acted upon by the actinic rays of radiographing apparatus. This emulsion is coated on to specially prepared paper. The paper is obtained by coating paper with calcium tungstate emulsified in gelatine, or other suitable medium. The record is made direct on to the sensitised material, and this obviates any printing, and only one development of the paper is required. Edwin Ebenezer Barnett, Wistowe, Hayes Town, Middlesex.

A LITTLE P.P.A. DINNER.—A very pleasant little function was arranged by the Professional Photographers' Association last week, in the shape of a dinner at Gatti's Restaurant, at which most of the members of the council with a few friends spent the evening together in a semi-formal way. Mr. H. A. St. George, president of the P.P.A., was in the chair, and in proposing the toast of the Association, reviewed the conditions of the past five years which, as he said, had been much less injurious to the photographic business than had been feared. In fact, although longer hours and harder work had been necessary, the increased demand for the photograph created by the war had had its satisfactory results. It was possible to say that, after eighteen years, the Association continued to grow in strength and good repute, and was in a position to meet and to deal with any problems that the future had for it. Mr. S. H. Fry, honorary secretary and treasurer, replied, and said, that while it was not possible to make a positive statement, it was most probable that the Association could hold a congress again next year. Other toasts followed, one being to the visitors, Messrs. Webb and Bell, of the Kodak Company, and Mr. George E. Brown, of the "British Journal," all of whom briefly replied. Letters of regret at inability to be present were read from Mr. Gerald Bishop and Mr. Edgar Houghton. Perhaps the outstanding feature of the speeches was in those by two country members of the council, Mr. F. Read, of Southport, and Mr. T. Chidley, of Chester, laying stress on the fact that photographers were putting aside their feelings of jealousy and aloofness, and were showing a great disposition to meet their competitors in a given town for the general advantage of their common interests. Mr. Lang Sims proposed the toast of the president, and Mr. T. C. Turner gracefully proposed the health of Mr. Alfred Ellis, by whom the arrangements for a most enjoyable evening had been made.

CATALOGUES AND TRADE NOTICES.

THE ADON LENS.—Messrs. J. H. Dallmeyer, Ltd., Church End Works, Willesden, London, N.W.10. send us a small booklet of the Adon lens of variable focal length from 13½ to 49½ ins. The booklet very concisely puts its finger on just those branches of work for which a lens of this kind is most useful, in addition to the ordinary purposes which a telephoto lens serves.

BARNET HELPS FOR BEGINNERS.—A forty-page booklet has just been issued by Messrs. Elliott and Sons, Barnet, Herts, in which Mr. W. L. F. Wastell has some very practical advice to give on exposure, development, and the making and toning of prints. Dealers should not omit to have a few of these booklets on their counters, where its most tasteful cover will attract attention. Single copies may be obtained on application to Messrs. Elliott.

ROSS LENSES AND CAMERAS.—Messrs. Ross have just issued their first catalogue of their photographic lenses and other apparatus which has appeared after the four and a-half years during which their works have been solely devoted to the requirements of the Navy and Army. The new list, which is illustrated with some striking photographs, gives full technical particulars of the Xpres, Combinable, Telecentric, and Homocentric lenses, as well as of the Ross portrait lens and the series for cinematograph cameras and projectors. Those who are buying a portrait lens which can be used to full advantage also for outdoor groups will find much assistance in the table on page 26, in which the dimensions of studio suitable for various lengths of the Xpres and the Ross portrait lens are set forth. The list gives the prices of various models of folding and reflex hand cameras fitted with Ross lenses.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JULY 19.

North Middlesex Photographic Society. Outing to Cassiobury Park.
Manchester Amateur Photographic Society. Outing to Dunham Parks.

MONDAY, JULY 21.

South London Photographic Society. "The Eyes of the Army." J. H. Jennings

TUESDAY, JULY 22.

Hackney Photographic Society. Slide Competition: "Woodland Sunshine."

THURSDAY, JULY 24.

Hampshire House Photographic Society. "Spotting and Retouching the Print." J. J. W. Carruthers.
Hackney Photographic Society City Outing.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

The last meeting of the session 1918-19 was held on Monday, July 7. Present were: Mr. Young (in the chair), Messrs. Aikman, Bambrick, Swan Watson, Ferguson, Campbell Harper, Johnston, Geo. Balmain, Lauder, Barrie, Scott, Moffat, Miss D'Arcy, and Miss Hatton.

The Chairman intimated that he had received an official letter from the Edinburgh College of Art appointing him instructor of the new retouching class which commences in October. An estimate of the cost of the construction of the necessary apparatus had been obtained and would be submitted to the college.

Mr. Johnston then submitted the report of the Apprentices Committee. He pointed out that the entire subject bristled with difficulties, and, the committee considered, was hardly a matter for a committee at all, but rather for the consideration of the society in general. Personally he was of the opinion that the nature of the profession of photography rendered it very difficult to arrange a definite scheme of apprenticeship. It was not a merely mechanical trade, but one which required a special aptitude in the individual following it out. A girl or boy, having commenced an indentured apprenticeship, might be found to lack the necessary aptitude for the business, and the master would then be left in an awkward position. In a one-man business a system of apprenticeship might be quite feasible, as the learner would be in a position to see and

acquire all the branches under the personal supervision of the employer; but in a larger concern, where the branches were divided into as many separate departments, the necessary moving of the apprentice from one to another, when he had just begun to be useful in the previous branch, caused considerable disorganisation.

The committee therefore considered that the best method would be to take on young people on trial. If they showed interest and ability they were bound to reach the top of the tree; but if they turned out otherwise it was then a simple matter to part company. Each junior assistant thus employed could learn thoroughly at least one branch. To push him, on the other hand, through every branch during a limited period had not only the disturbing effects before mentioned, but left the assistant with no thorough knowledge in any one department.

Mr. Campbell Harper corroborated these remarks.

Mr. Young thought that the lack of a good apprenticeship system was responsible for much of the inefficient help complained of at the present time. He pointed out that the apprentice was not to be considered as part of the working staff, but rather as an extra. He quoted figures which he had procured recently regarding other industries. The house painters had an apprenticeship of six years, with salaries ranging from 11s. 6d. per week in the first year to 24s. in the last year. Bookbinders and printers had a term of seven years, with salaries from 12s. to 42s.; engravers, six years, with salaries from 9s. to 37s.

Mr. Scott thought that to train a man in one department only was a great mistake. The knowledge of other branches, he pointed out, was of great use in the carrying out of the particular branch in which the assistant might finally specialise. He did not, however, favour a system of indentures.

Mr. Young thought that indentures were necessary towards obtaining security. Otherwise an apprentice was liable to leave as soon as he thought that he had gained a little knowledge.

Mr. Swan Watson explained the system under which he had always worked. He had a term of four years, the first two being spent in the studio, dark-room, and in acquiring a knowledge of enlarging. Then eight months were spent in the printing-room, eight months in the retouching department, and eight months in the finishing-room. All his apprentices were taken on six months' trial, during which the apprentice could leave of his own free will, or he could be dismissed if found to be unsuitable.

Mr. Young thought that a set-down training would have the advantage of attracting a better class of boy.

Mr. Moffat then moved that, in view of the foregoing opinions, a new committee should be appointed which would include those who desired to keep apprentices, and who could draw up a scheme to be approved of by the society, and which would remain as a standard system for all those employing apprentices.—Mr. Campbell Harper seconded.

There being no amendment, the following committee was appointed:—Messrs. Swan-Watson, Johnston, Bambrick, and Campbell Harper. Mr. Watson was appointed convener.

Mr. Campbell Harper moved that the proposed professional exhibition should be proceeded with, provided a minimum of twelve supporters could be obtained.—Miss D'Arcy seconded.—Mr. Barrie, who did not favour the exhibition, pointed out the difficulty of making it sufficiently interesting to the public, and suggested that the exhibition be an open one.—Mr. Johnston admitted that it would not be one which would attract amateurs or those interested in photography, as such, but he was of the opinion that the general public would be interested. The committee were instructed to seek the necessary support.

The committee then placed before the meeting a proposal to raise the annual subscription to one guinea in order that the society might rent a private room in which a small reference library might be inaugurated. It was pointed out that this matter would necessarily be brought before the annual general meeting in October. Those members present unanimously agreed to support the motion.

A letter was read from the Secretary of the Birmingham Photographic Society requesting advice as to whether there was a likelihood of much employment for demobilised soldiers in photography. The Government had approached the Birmingham Society with a request to train men for that purpose. It was the general opinion of the meeting that the market would presently be glutted with

assistants, and that the large number of demobilised Air Force men who had learned some photography in that service would also swell the numbers.

The meeting then closed.

Correspondence.

PERCHLORIDE OF IRON FOR MAKING RAPID PHOTO-TRANSFERS FROM TRACINGS.

To the Editors.

Gentlemen,—This salt is curious, as it works in complete anti-thesis to the bichromates; the action of light, instead of hardening the colloid film, makes it soluble. If a solution is made up similar to the one used for the old gallic-iron water-bath process, and a piece of stout litho paper is coated by sponge and immediately dried and exposed under a fairly transparent tracing for $\frac{1}{2}$ —1 minute in the sun, then inked up with photo-transfer ink and developed in cold water, an excellent transfer is procured.

There seem to be two kinds of perchloride, however: an acid and a neutral one. The acid one will not do for the above. Another curious thing is the fact that if the paper is kept for some time after exposure it gradually goes back to its general insolubility and has to be exposed again, all trace of the first exposure becoming lost. The solution I used is the one given in the B.P. Almanac for ferro-gallic paper.

Colombo, Ceylon.

W. WALL.

DRY-MOUNTING WITH A COPYING PRESS.

To the Editors.

Gentlemen,—Apropos your paragraph on dry-mounting a small number of prints, the method I use may be of assistance to others, who, like myself, do not mount a sufficient number to justify the expense of a dry-mounting machine.

I purchased a second-hand foolscap letter-copying press. I place an old polishing plate in the domestic gas oven, and heat until it has attained a temperature in excess of that required. The print is tacked on to the mount in the usual manner, using a laundry iron for the purpose, and is then laid face downwards on a pad of blotting or other paper. As soon as the plate is heated, I put it on the back of mount and quickly place the whole in the copying press and screw down; after about three minutes, the print is ready for removal.

The secret of success lies in getting the plate heated considerably in excess of the actual temperature required, and allowing it to remain in the press until it has cooled below the correct temperature. By this method the correct temperature occurs at some period, and ensures proper fixation. I have mounted a number in this way, and since following the above method I have had no failures, even when using multiple mounts and mounting two tints and print at one pressure.—Yours faithfully,

P. C. TAYLOR.

Carlton, John Street, Ellesmere Port, Birkenhead,
July 15, 1919.

REVERSAL IN DEVELOPMENT.

To the Editors.

Gentlemen,—In reference to correspondence on reversed images which appeared in your columns during May and June this year, we think the following remarks and the specimens forwarded herewith will prove of interest.

A short time ago one of our customers sent us several positives of unusual kind, obtained when developing some snapshot pictures with amidol. We are sending you two of our customer's negatives and two made by us possessing similar characteristics—viz., a

coloured positive image in the lesser exposed parts of the plate with a true negative image in the more fully exposed parts; the colour is due to dichroic fog of a very pronounced character; the plates were very much under-exposed.

We were successful in imitating our customer's results by forcing the development of seriously under-exposed plates in a strong amidol or metol-hydroquinone developer, which was purposely contaminated with small amounts of hypo or other solvent of silver bromide. The explanation of the formation of a positive image is obvious: for, dichroic fog, which forms readily when development is carried out in the presence of a silver bromide solvent, is restrained like ordinary black fog by alkali bromides. The amount of dichroic fog at any point on the plate will be, roughly, inversely proportional to the amount of negative image present, since in the development of the latter alkali bromides are set free in the film early in development, and tend to prevent the formation of the dichroic fog, which develops later.—We are, yours faithfully,

ILFORD, LIMITED

Ilford, July 11.

A PROFESSIONAL PHOTOGRAPHIC ASSISTANTS' ASSOCIATION.

To the Editors.

Gentlemen,—I have just returned from holidays, and on reading the three numbers of the "B.J." accumulated in my absence I was interested to see the suggestion made at the P.P.A. meeting ("B.J.", June 27) that assistants should form an association, and that this week (July 11) Mr. A. Hamilton Smith is proposing a meeting in London to discuss the project.

For us assistants in the north it is difficult to get to London, and I should like to suggest that in various parts of the country centres should be formed—say, Birmingham, Manchester, Leeds, Bristol, Edinburgh, Glasgow, etc. The assistants in these districts could arrange meetings amongst themselves for discussion of the proposal. Once these centres are formed it should be a simple matter to compare results and combine. The attempt has been made before to form an association, but failed, mainly, I think, because of the inability of assistants to get into touch with the moving spirits. If some energetic and interested individuals will do their utmost in their own districts to get their fellow assistants in touch with each other personally, I feel sure something will be achieved which will be worth our while as individuals and as a class. I personally am willing to do my bit in the Manchester district should anyone think it worth while spending a little time in order to create, if possible, a little better feeling between employers and employees than the late correspondence in the "B.J." and my own sixteen years' experience have shown to exist. I shall be pleased to hear from anyone interested. Yours truly,

WM. ASPDEN.

165, Church Road, Smithills, Bolton, July 11, 1919.

Commercial & Legal Intelligence.

NEW COMPANIES.

EASTMAN KODAK COMPANY.—The directors have declared an extra dividend of 5 per cent. upon the Common Stock, payable on September 1, to stockholders of record at the close of business on July 31.

AROUND THE TOWN, LTD.—This private company was registered on July 3, with a capital of £250 in 1s. shares. Objects: Photographers' photographic apparatus manufacturers and dealers, etc. The subscribers (each with one share) are:—J. W. Myatt, 37, Victoria Road, Tipton, accountant; H. S. Myatt, 12, Crompton Road, Tipton, iron-works manager. Table A mainly applies.

PHOTOGRAPHIC SERVICE CO., LTD.—This private company was registered on July 2, with a capital of £2,000 in £1 shares. Objects: To acquire the business of photographic and general printing carried on by J. de Lysle, at 267, High Holborn, under similar style. The subscribers (each with one share) are:—J. de Lysle, 267, High Holborn, W.C.1, photographic artist; A. Hunter, 115, High Holborn, W.C.1, solicitor. The first directors are:—J. de Lysle and A. Hunter. Registered office: 267, High Holborn, W.C.1.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

R. B.—About the best handbook you can get if you are quite unfamiliar with photography is Watkin's "Manual," which you can buy for a 1s. or 1s. 6d. at Messrs. J. T. Chapmans, Albert Square, Manchester.

P. H.—From the lighting of the faces, it would seem that your light is too low. Try raising it on a platform of boxes. A diffuser would improve matters, and, if thin, would not appreciably lengthen exposure.

H. C.—We advise you to purchase the handbook "Photographic Lenses," published by Messrs. R. and J. Beck, 68, Cornhill, London, E.C., price 1s., which is full of information regarding lenses and their focal length.

R. S.—Very much depends upon the focal length and aperture of your lens. As a general rule, a cubical or conical box 10 ins. or 12 ins. square fixed on the lens hood will answer well. If you could make two boxes, one sliding in the other, you could adjust the distance. You can, of course, judge the effect on the focussing screen.

A. N.—The Dallmeyer lens has a value of about £5 10s., and the Ross of about £2. As regards the Meagher camera, it is possible only to give a very wide price, since patterns of this maker varied considerably. We should price the 10 by 8 Meagher at from £4 to £8, if in thoroughly good condition. The Lancaster "Instantograph" may have a value of from £2 to £3. All these prices are to a direct purchaser; dealers will give little more than half.

G. W.—If you place three 1,000 c.p. half-watt lamps about 7 ft. from the floor, except the front one, which should be placed as high as possible, you should then get good lighting and quick exposures. A white reflector should be put behind each lamp and a thin oalico diffuser in front. Care should be taken that no direct light reaches the lens. For a studio such as you propose the walls should be rather light grey or very pale green. This will shorten exposures and prevent heavy shadows.

N. N.—Brass will not cause any material damage to an acid hypo bath, but as stoneware sinks are supplied fitted with an outlet closed with an earthenware plug, we certainly think it would be better to have this fitted in preference to any metal socket and plug, which is certainly liable to become leaky through the continued action of an acid fixing bath. Messrs. Griffin, as outfitters of chemical laboratories as well as photographic workrooms, could supply sinks of this type, which are, in fact, quite common.

P. W.—If the rear lens is twice the focal length of the complete objective, as is the case with the majority of lenses, the exposure will be four times that required with the same stop in position when the complete lens is used. Some lenses have the rear component more than double the focal length of the complete lens, in which case the exposure will be correspondingly more than four times; but, for practical purposes, you will not be very far out in taking it at four, that is to say, your half-second will be two seconds

C. T.—We think the cause of your troubles lies in your practice of using an alum bath after fixing with only a rinse between. Unless prints are given really a thorough wash in four or five changes of water between fixing and aluming there is liability to fade, particularly if fixing has not been thorough. We advise you to use a fixing-hardening bath compound of hypo, alum, sulphite, and acetic acid, and made up according to the formula given by the paper makers—for example, the Kodak Company's working instructions for Velox. If you do this, and particularly if also you have two fixing baths in use and pass prints successively through them, we think your fading defects will disappear.

E. S.—For an all-round light we do not think that you can do better than to fit up an incandescent burner and a watchmaker's or engraver's globe. The latter is a spherical water-bottle on a stand, which throws a strong beam of light on your work while keeping the flame itself at a considerable distance from your head. Some workers tint the water blue with a little sulphate of copper; this would be necessary with an oil light as this is too yellow for colour work. You can get the globes from any dealer in watchmaker's tools, such as Plucknett and Co., of Poland Street, Oxford Street, London, W. For retouching you could throw the beam on a white or opal reflector.

G. C.—Section III. of the Retail Businesses Licensing Order is pretty wide, for it says that "any licence may be issued subject to such conditions and restrictions as may be contained therein. Nevertheless, we think there is nothing in the Order which authorises restrictions to be placed upon the way in which a licensed business shall be carried on—that is to say, of a kind such as you mention. If it is made a condition of the licence that you shall carry on the business in your own name, we hardly know what you can do, because, if you protest against it they may take the licence away from you, but we do not think they would. We think it is a case in which they have exceeded the powers granted them by the Order. But if you trade under the name of _____ you must register this name at the office of the Registrar of Business Names, 39, Russell Square, London, W.C.1. The cost of registration is 5s., and certain requirements apply to firms who are registered. The chief of these is that the real names and any former names of the partners shall appear on the stationery and business literature of the firm, but it is not necessary that the names of the partners should appear on the facias of the premises or be otherwise displayed to the public.

THE PHOTOGRAPHIC CORRECTION OF NEGATIVES TAKEN OBLIQUELY. By L. P. Clerc	428	CORRESPONDENCE— Flattening Postcards of Prints ANSWERS TO CORRESPONDENTS	435

SUMMARY.

In his article this week "Practicus" deals with the posing of the head, a subject upon which a volume might be written. But the article contains many suggestions to the photographic portraitist. (P. 422.)

The recent paper by Mr. Walter C. Mann, chemist to Messrs. Thomas Iltingworth and Co., gives some indication of the measures which makers of printing papers take to avoid defects due to impurities in the paper base. (P. 426.)

The relation of texture in a portrait to the lighting of the sitter and the general question of tonal quality in portraits are the themes of a contribution to the "Photographic Journal of America." (P. 424.)

In a leading article we refer to the qualities which are desirable in studio shutters where the maximum speed may be assumed to be about 1/10th of a second. There is still room for improvement in shutters of this type. (P. 422.)

The death is announced of Mr. Walter D. Welford, at one time sub-editor of "Photography" and an early enthusiast in hand camera work. (P. 434.)

Some forecasts of Lord Montagu include the making of minute photographic reproductions for transmission by aeroplane post. (P. 421.)

The optical conditions for the correction of a negative taken from an aeroplane with the axis of the lens at an angle from the vertical have been worked out by M. L. P. Clerc for the purpose of designing a rapidly-operated correction camera. (P. 428.)

Particulars of a new type of triplet lens with which apertures of f/2 and larger may be obtained will be found under Patent News. (P. 430.)

A correspondent describes the method of flattening prints or post cards single by hand. (P. 435.)

While the Professional Photographers' Association adopts the policy of admitting the right of every photographer to be a member (p. 432), the Lancashire Society of Master Photographers considers it advisable to consider applications for membership. (P. 433.)

Lack of definition in prints through want of contact with the negative from one cause or another seems to be a more prevalent defect nowadays. (P. 422.)

The amateur may be made a source of profit to the professional not only through his orders for developing and printing, but through portrait business which he may introduce. (P. 421.)

The War Museum is inviting contributions of photographs of historical interest in connection with the war. (P. 427.)

EX CATHEDRA.

Amateurs' Orders. We think that the common idea that the amateur has always been the enemy of the professional is quite a fallacious one, and the attitude of hostility which is frequently taken up is therefore unjustifiable. Mr. F. M. Sutcliffe recently gave an amusing account in a northern newspaper of his experiences with amateur customers, after a launch had taken place at Whitby, and his observations should quite dispel the notion that every amateur is a potential rival. As a matter of fact many photographers find it a paying proposition to cultivate the acquaintance of the amateur, not only for the value of his orders for developing and printing, but for the sake of the portrait and other business which is introduced. One point we need not emphasise, and that is that no attempt to compete with chemists and dealers in respect of prices must be made. The Kodak scale should be the absolute minimum, and when possible a superior class of print or mounting should be brought forward. The well-to-do amateur who can afford to spend one or two hundred pounds on a trip will not be afraid of an extra fiver to have his results developed and finished in the best style. If the photographer takes an intelligent interest in his customer's work he may be able to give him hints which will enable him to do better next time, and he may possibly be able to supply better apparatus. The khaki boom is nearing its end now, and the prudent man will not miss any chance of adding even small amounts to his annual turnover. The semi-amateur who retains a well-paid post in a Government office or bank while actually competing with the professional is not likely to seek out the latter, but the genuine one only needs to be assured of a welcome and he will gladly do so.

Photography and Aeroplane Post.

If the forecasts of Lord Montagu come to be realised photography will soon be playing an important part in the application of the aeroplane to the carrying of mails and to the rapid and economical distribution of information. In a paper read recently before the Society of Arts on aviation as affecting India Lord Montagu looked forward to an aeroplane mail service between England and India in which letters would be carried at the rate of 2s. 6d. per ounce, the ounce permitting of a message of 5,000 words in length, which would cost £416 at the present prices of telegraphic communication. Moreover the aeroplane message could be conveyed, without mutilation in transmission, in forty-eight hours as compared with four or five days for the transmission of a telegraphic message of this length. To these computations Lord Montagu adds the suggestion that photography will be called into service for reducing the size and weight of typed or printed messages to an exceedingly small compass, the photographic reproduction on a

minute scale being enlarged by the recipient. In this forecast of what photography and the aeroplane may accomplish in conjunction he includes the reproduction in facsimile of a complete copy of the "Times" in India within three days of publication in Printing House Square.

* * *

Chromium Intensifier. It is, in our experience, quite rare to find a professional photographer who uses the chromium intensifier; the mercury and ammonia method with all its faults is almost exclusively used, yet the chromium method, in the majority of cases, is so greatly superior both in ease of manipulation and in quality of result, to say nothing of permanence, that only a trial is needed to secure its adoption. The formula will be found in the Almanac, so that it is not necessary to repeat it here, but merely to point out where the advantages of using it come in. In the first place bichromate of potash, although poisonous, is not nearly so deadly as mercuric chloride, and the colour of the solution is a further safeguard. No one is likely to drink even a very dilute solution of it in mistake for anything else; secondly, it is cheaper and can be readily obtained at an oilshop if the local chemist happens to be out of stock. Other advantages are that it has less tendency to choke up details and to give rise to staining, while the necessary washing between bleaching and blackening takes much less time, and, moreover, it is easy to see when it is complete, so that stains from this cause are avoidable.

* * *

Bad Contact. A little point which has several times come under our notice lately is that of unsharp prints caused by a want of proper contact between the negative and the printing paper. This would seem to be due to two main causes, the thickness of many of the brands of paper now used and weakness of the springs of the printing frame. Carbon printers are quite alive to the danger of faulty contact, and as a rule prefer to use the old "box" form of frame, in which the pressure is applied by means of strong springs fitted to hinged cross-bars. In these days of feverish haste it is perhaps too much to expect bromide printers to use this pattern, but they should certainly see that the springs, frail as they are, of the ordinary frames are in good condition, and, if not, that they are promptly renewed. In many printing boxes the pressure-pad is simply held down by the hand, and it sometimes happens that a small chip or piece of card prevents it from going home properly, so that one side of the paper has practically no pressure upon it. For all prints over half-plate size a stout felt pad should be placed behind the paper before putting the back of the frame in position. This takes but a few seconds, and makes even contact certain. In some groups which recently passed through our hands some of the faces were far from sharp, that this was not due to the negative was proved by the fact that the unsharpness was not always in the same part of the print.

* * *

Enlarged Negatives. When a considerable number of enlarged prints are required it is generally desirable to make an enlarged negative, for not only can it be printed in an ordinary printing box, but it can be carefully retouched and matt varnished if need be, thus saving an enormous amount of spotting on the prints. It is easy to make a transparency on an ordinary slow plate, giving full exposure and keeping the image rather thin. Few photographers possess any arrangement for making the enlarged negative by daylight, but fortunately it is easy to do it in the ordinary enlarging lantern. To avoid waste of large plates a test exposure can be made by fixing

a quarter-plate so as to receive the densest portion of the image, and from this the correct exposure can easily be estimated. Naturally a plate of the same make and speed will be selected if possible, although if the H. and D. or Watkins numbers are the same the actual make of the plate should not be of great consequence. If the original subject has much contrast it is a good plan to use backed plates for both positive and negative, as this will allow of very full exposures being given without causing halation. It is not necessary to provide any special holder for the plate, as three or four glass push-pins will do this effectively, allowing the plate to be placed at an angle if it is needed to alter the position of the subject.

SLOW SHUTTERS.

THE attention of makers and users of exposure shutters has been so much engrossed by instruments designed to give exposures of a small fraction of a second that the slower varieties such as are mainly used for studio work have been somewhat neglected. The construction of these has always been extremely simple, and so long as the flap or flaps could be opened somehow no question as to the desirability of saving effort seems to have arisen. The faults in the design of most studio shutters are that the moving parts are comparatively heavy, and that they are not balanced in any way, so that when the motive force is applied by means of a rubber bellows or teat great pressure is necessary to cause the shutter to function. Another place at which much power is wasted is in the bearings of the spindles upon which the flaps are fixed. In many cases the spindles are made of wood, with a small metal pin driven into the ends: a pin working in a plain hole in the wooden shutter casing is a truly primitive construction. It might be contended that the arrangement is efficient for the purpose in view, and the contention would be just if the only object were to make a shutter which would open somehow; but almost every month we find fresh advances in the speed of the plates used for portrait work, so that the action of the shutter assumes more importance. Studio work calls for efficiency in the action of a shutter just as much as press photography does, but in a different direction. A great desideratum is evenness of exposure over the entire plate: any fault of construction which causes slow opening and closing militates against it. Let us take the case of a single flap shutter, which is usually placed so that the flap is raised to open it. If such a shutter be used for a seated figure the head will be the first part of the subject to be uncovered and the last to be covered. When exposures were long, this was of no consequence, but now half a second or even less is commonly given, half of this short time may be lost on certain parts of the plate which may or may not be better for being under-exposed. This defect is aggravated in many cases by the shutter being fixed a considerable distance behind the lens.

It has always been a matter of wonderment to us that no British maker has sent out a simple sector shutter on the lines of those known as the Packard Ideal, Low, and Central. In these there is a rapid opening from the centre, the leaves remain balanced at the open position, and they close quickly when the air pressure is withdrawn. Moreover, the shutter can be set open for focussing without putting any strain upon the rubber ball and tube, and even a leak in the release does not seem to impair its working.

The introduction of the Bowden wire or Antinous release has removed one great trouble in shutter manipulation, viz., leaky balls and tubes; but the cable is not so smooth in working as a good air release, possibly owing to the

very uncomfortable shape of the plunger, which has to be held carefully and cannot be picked up anyhow like a rubber ball.

The uneven action of the flap shutter was utilised many years ago by landscape photographers, who used what was known as a sky-shade shutter in front of the lens. With this it was possible to vary the proportions of exposure given to foreground and sky to any desired extent, while by turning the shutter sideways such subjects as street views with one side in sunlight and the other in deep shadow could have the exposure graduated to suit the lighting. In order to secure satisfactory results the shutter must be lifted by hand, and for this purpose we have seen nothing better than a piece of thread with a small boot button on the end. This obviates nearly all vibration, and may be operated from any convenient position. A very ingenious blind shutter answering the same purpose was made many years ago by Mr. H. Window. It consisted simply of a black linen blind running over a roller in a casing in which were openings for the lens hood. A string was attached to each end of the blind, and all that had to be done was to pull the shorter string when one end of the blind went up till the lens was fully open.

Then, on a resumed pull on the cord, the other end of the blind descended and terminated the exposure. This is an excellent pattern of shutter for landscape work—we had one in use for years, and if we remember rightly the shutter was one of the many really practical accessories which were placed upon the market years ago by Mr. Tylar, then of Birmingham—but in the studio any shutter which needs the same attention in operating and requires one to be near to the camera is, of course, useless. We have still some way to go in the design of a studio shutter which shall combine within itself the qualifications of great simplicity of construction, even illumination of the plate at what may be termed almost snapshot exposures, and what is of the first importance for the purposes of many photographers, silence in action. In this last respect it is just as important that the shutter should be silent in its action after exposure has been completed as in opening and making the exposure. The aim of the shutter constructor should be to do his part towards destroying the idea that the camera is a machine in action. From this point of view any click of shutter mechanism, even when it comes after the exposure has been made, must be regarded as an undesirable feature.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).

Plates and Their Work (July 11).
Apparatus Repairs and Renovations (July 18).

POSING THE HEAD.

MANY young photographers start on portraiture heavily handicapped by a lack of training not only in the principles of composition and lighting, but in the faculty of observation. If all men were like Apollo and all women like Venus portrait work would be simple, and it would be difficult to make an ungraceful representation, no matter how carelessly the point of view were chosen. But, unfortunately perhaps, the average sitter is far away from the ideal in the matter of looks, even the most comely possessing some peculiarity which, if accentuated by bad posing, will go far to destroy their claims to beauty. The first thing, therefore, which the beginner has to learn is to use his or her eyes so that it is easy to see in what respects the model differs from the ideal, and then to arrange the pose so that these shortcomings are minimised.

The first thing to be learned is to recognise a bad picture when you see one. If you cannot do this there is little hope of improvement. Unfortunately many excellent operative photographers never seem to be able to do this, the technical quality of the negative and print filling all their horizon. Such

folk would do excellently with motor-cars or portmanteaux, and should keep to such subjects, leaving portraiture to those whose manipulations may be faulty, but who possess in some degree the power of artistic perception. Many successful portraitists are sadly lacking in technical knowledge, and could not hold a situation as assistant operator for a week, but they know a picture when they see it, and have worked along by slow degrees until they have attained their goal, while the technical expert has to be contented with such sitters whose perception of art is on a level with his own, perhaps occasionally "fluking" a success without knowing he has done so.

I do not propose to touch upon lighting or perspective, but to deal in as simple a manner as possible with the peculiarities of the face, and I would impress upon the novice that his study must be incessant, not necessarily laborious, but as a matter of habit; in every street, shop, train, or bus there are objects for study, and the question as to the best way of treating them should always be uppermost. I think that I have before mentioned the case of a clever retoucher I knew who told me that

she always mentally retouched her *vis à vis* in the tube on her way to and from her work; that is the right spirit, and one that leads to success.

We must never forget that every face has two sides, and that in ninety-nine cases out of a hundred these are widely different, that is to say, that the nose usually curves to one side or the other, that the eyes are seldom the same in size or position, and that the mouth is also more or less unsymmetrical. Besides these easily recognised features there are more subtle differences in almost every muscle, and particularly in the contour of the cheek. Of the general pose of the head little can be said except that it should be well balanced upon the neck, and that there should be no appearance of strain upon the muscles. In these times much more latitude in position is allowed than was formerly customary, and we see many pictures of ladies peeping in from the side of the picture in a position which would have horrified the old portrait painters. There is one mistake which must be guarded against, and that is of having the head turned in one direction while the eyes are looking in another. This is not always the photographer's fault, for if not carefully watched the sitter will turn the eyes to see what is going on at the camera; therefore it should be watched for at the moment of exposure.

The face and shoulders should never both squarely face the camera. If a full-face portrait is desired the body should be slightly oblique to the lens, while in three-quarter-face poses the shoulders may be nearly, but not quite, square.

The eyes, I have already said, are seldom symmetrical, and as a rule it is advisable to turn the larger one to the camera. If one eye is higher than the other it should preferably be taken, but if these two characteristics are not on the same side of the face the operator must make his choice between them. If the eyelids have a tendency to droop the sitter must be told to look up without altering the position of the head; while a tendency to stare must be remedied by looking down. Do not let the sitter know your object in directing the glance of the eyes, as this will probably lead to a noticeable effort to open or close the lids. In the case of sitters who habitually wear spectacles, these should be retained, as the apparent size of the eye is altered by them, and a portrait taken without them may not be approved. Many of the old photographers kept a stock of unglazed spectacle frames for the use of sitters to avoid reflections, but for the reason I have given this practice is not to be commended.

The nose requires special attention, as the whole character of the portrait may be influenced by the choice of sides. As a rule, the side which gives the straightest line should be presented to the camera. If, however, this position is incompatible with the best view of the other features, we must rely upon the retoucher to remedy the defect. At times it is in-

evitable to avoid calling in the aid of the pencil and knife, but, as a rule, the photographer should forget that retouchers exist. They will still have their work to do, but the more that can be achieved by the lens and the less by hand, the better for the likeness. In the case of long noses, the head should be slightly raised, or, better still, the camera lowered, as this will not affect the pose of the head as a whole, while short or *retroussé* noses need the head to be depressed or the camera raised. It is as well to remember that the camera has a rising front, which can often be used to advantage instead of giving an excessive tilt to get the figure properly centred upon the plate.

The mouth is difficult to deal with, especially where it is habitually open. As a rule, any attempt to alter this results in failure, so that it is better to take a three-quarter view, and, if the nose will allow it, to depress the head a little. Fortunately, the open mouth and snub nose usually go together, so that this can generally be done. It is often complained that the mouth appears too large. This is really due to the fact that there is a shadow from the upper lip beyond the actual opening of the lips, which in the print appears to be a continuation of the opening. This shadow may be lightened by retouching. It is most noticeable when a little excess of top light has been used.

The cheeks must, of course, be considered in conjunction with the rest of the face, but care should be taken to get the most pleasing outline. If the cheeks are at all hollow and the cheek bones high, a nearly full-face position is best. As a general rule, it is not advisable to let the tip of the nose fall upon the outline of the cheek. It should either be well within the face or project beyond it.

Of profiles, little can be said except that, particularly in the case of ladies, it is not advisable to have the head exactly level, a slight turn up or down usually giving a more pleasing effect. Beware of making the ear appear too large. Ears are usually large enough in nature, and a short focus lens intensifies the defect. The forehead, while hardly a feature, calls for its share of attention. A high forehead may be shortened by tilting the head forward or by raising the camera, but this must not be done with a bald head. A low one is best taken from the level.

The appearance of the neck is greatly influenced by the height of the camera. A low position lengthens the neck, and a high one shortens it.

It will often be found that all the conditions for securing the best rendering of each feature cannot be obtained at the same time. Then the judgment of the photographer must come into play, and he must decide which can best be sacrificed to the general effect.

PRACTICUS.

TONE AND LIGHTING.

[The anonymous author of the article in our contemporary, "The Photographic Journal of America," which we reprinted in our issue of May 16 last, has followed it by another in which his theme is that constantly present in the mind of the portrait photographer, namely, the influence of lighting upon the tonal quality of a portrait, together with the correlated question of the rendering of textures in a photograph.—Eds. "B.J."]

It is by no means imperative that the subject be placed at apparently great distances from the light for obtaining tonal qualities, nor for the luminosity of colour values in our monochrome work. All this is possible when the subject is very near the light.

When working in a room without diffusing curtains, where only opaque ones are employed, as is the custom with many of our leading men, it becomes necessary to get considerably away and from under the light, to prevent undue accents.

When the skylight is provided with *clean* and *white* curtains (not dusty and yellowish white), work can be made much nearer the light. If the dark curtains are pulled down directly overhead the chair can be placed under the skylight. If the white head screen is turned at such an angle that it will be interposed between the light and the sitter. This will tone down the light considerably on account of its close proximity to the subject. This, to some, may appear to produce extremely flat results, but if the curtains and the cheese-cloth

head screen are clean, the light will be pure, only much softened. It is very obvious, however, that the use of a reflector (even of a medium plain ground) is rendered less necessary under such conditions.

With the lighting thus arranged a side screen with an adjustable and extended arm may be interposed to tone down the ear nearest the light. It may be covered with coloured cheese-cloth, loosely thrown over to produce any desired effect. Very fine results are thus easily obtainable. A "low-tone" effect will be produced with the isolated white of the ear thrown back in its proper position in drawing, or perspective. The drapery and clothing modified by the draped extended arm of the side-screen will also be in their proper position in attractiveness. Tonality is thus obtained, and the key of tone produced may be medium, low, or very low, dependent upon the nearness of the subject to the screened skylight, and the location of the interposed white head screen, used to tone down the light that falls upon the head and figure.

Pictures made in this way have certain advantages over those made at considerable distance from the light, as there seems to be more solidity to the portrait.

The writer thinks it is conceded that more solid effects are produced nearer the light than at a great distance away. There certainly should be a feeling of actual substance in the human figure. This should always be remembered when making pictures. There is danger, however, in getting too near the light, as well as going to the other extreme.

Too much stress cannot be given to the importance of having the light as pure in quality as possible. Cut down the power of its direct rays. Be careful there is sufficient of it for required illumination, but do not use dust-covered and discoloured screens or curtains. These would render the light weak and dead in quality.

Soften it, but have it as pure as you can make it. This gives substance to the resultant negative. These low-toned effects then will be found to need only a few seconds' exposure with open lenses, to be *fully timed*. Free exposure should always be given if you wish to produce in the negative that which you have taken pains to arrange in your composition.

There are various methods employed for the production of low-toned work, especially by the strictly pictorial workers. But it seems to the writer that the professional should work along lines that will produce these results with a minimum of exposure.

One of our most highly esteemed and successful pictorialists, with an international reputation, who most unfortunately has recently lost, by fire, his entire collection of negatives and prints, often placed his sitters, if I remember him correctly, some thirty or more feet away from a comparatively small window in the slant roof, and where he was obliged to give about a minute's exposure. It may be added that the selection of this shade and the use of this special light were for a definite purpose in his method of work. He also used other windows nearer at hand, not confining himself to the one on the roof.

With those subjects who kept fairly still his results were decidedly pleasing. His methods of work embodied a wide range of pictorial principles which were always a pleasure to see, yet the writer is aware that there are many others of this extreme school of pictorialists who plan to produce work with shorter exposures.

Textures.

The ability of the artist of the brush to produce textures largely determines his standing as a *painter*, and although he may be eminently successful in this sense it by no means follows that he has even fair ability as an artist of the *grand class*. He may be simply excellent in his technique as a painter in just the same way as is the better class of photo-

graphers who work solely in the old school methods. They may likewise be excellent in technique which is purely photographic, yet devoid of any artistic qualities, with which is identified the more modern movement in photography.

The photographer, like the painter, may try to put aside his technique in his efforts toward the acquirement of the more worthy and higher standard of his art, but the ability to do so depends much upon his temperament. Late in life this is seldom done. This, however, should not be the case, for it is at this age that his work is liable to be passed by. He should get into the procession, and march with the youngsters. With the aid of his riper judgment, he would likely avoid some pitfalls into which his younger and more energetic brother might fall, thus equalising matters somewhat on the way. Texture is the reproduction in pictures of a likeness pictorially of those things painted, or in our case photographed.

Surface Textures.

With artists, texture painting seems to be indissolubly linked with surfaces and brush work, on the theory that woollen fabrics, rugs, etc., by their powers of absorption or reflection of light, take on a textural appearance that calls for attention to surfaces and brush work, different from that produced by silks, cotton, or polished wood, etc.

In photography, a great deal of this is rendered unnecessary, even to those desirous of following the painters' work in its fullest details. Pictorially, these things are easily recognised in our product as resembling the original subjects, be they hard, soft, smooth, or rough, regardless of what the surface of our medium of expression may be.

We photograph the silk, cotton, cloth, polished wood, and the rug all on the same surface of paper, and can very easily reproduce their pictorial appearance. The painter interprets a mirror, mantel, polished wood, etc., with a different surface from that he does for a rug.

We can reproduce the face, hat, coat, shoes, and furniture, so there will be no mistake in recognising them, whatever the medium used, *providing it is right in the negative*.

To the use of surface texture in painting is doubtless due the introduction of gum-bichromate printing in photography. The successful gum worker, by his handling, has given a distinctive individuality to his work which is very pleasing. This is practically the only process of brush and surface work that photographers have extensively practised, and is in use only by a limited number. The glycerine-platinum development is not practised in this sense, but only for individual effects pictorially, and entirely separate from surface texture.

Whether we employ carbon transfers or special platinum coating makes no difference; *for whatever the surface* may be the result is the same.

Following the painter, therefore, in attention to surface texture, in the practice of photography, is a matter that need not concern us. The question resolves itself into the selection of the best *uniform* surface, whether it be polished, matt, smooth or rough.

Textures Pictorially.

With the textures of the surface eliminated, our relation to "texture" pictorially reproduced in the negative, so that it will in the print be a faithful likeness of the subject photographed, is what is to be considered.

Since the lens is so prone to reproduce every speck or spot so faithfully and indeed slavishly, the question naturally arises, "Can this tendency be overcome when desired?" Certainly it can.

I cannot better answer this than to refer to an incident that occurred at my studio this morning.

I received a visit from a very bright, clever, young pictorial worker, who was advised by one of my New York friends to

call upon me with his samples. He desired to secure a position where pictorial work was the essential requirement.

One of his two best pieces was a working man, wearing a soft, dark felt hat and working clothes. The felt hat shaded his eyes, but the shadow was luminous and the texture of his forehead and face was well rendered. So were his clothes. The lighting, as a whole, was excellent, likewise colour; tonality, on the whole, was good, except in one spot which presented unity, and this was the point of the nose, which being too highly accented had thrown it out of tone. The picture was made on a medium dark ground, and by reducing the edges of the plate, he had much improved what would otherwise have been a monotonous background. He had given variety by reducing the corners of the plate and by throwing the centre of interest to the face to which contrast has been added by the shadow of the hat.

The light on the nose, which by being forward had naturally here received an excess of light, still further assisted in the concentration. This was unfortunate, and injured the picture.

There were one or two minor things, rather unimportant, that might have been improved upon, yet, on the whole, it was very pleasing and exceedingly creditable.

I had commented rather unfavourably upon the symmetrical

appearance of a section of the shadow on the ground near the hat. This was procured by "faking," and made the hat itself too prominent at its darkest point, against this light place in the ground. I suggested that the reducing should be done there a little also.

I then asked him what my friend had said about the picture, and was informed that some of the points I had criticised had been remarked upon by him also, but that he had dwelt more especially upon the texture of the hat as being the same as the shadow side of the face, and that the shadow could as well be the hat, or *vice versa*, in as far as they represented the likeness of the original.

I thought I had looked for "texture" myself, but immediately noted that I had been remiss in this respect. Representation of texture is one of the strong points of this absent critic, who is very quick to note its absence. This immediately brought to my mind the advantages to be derived by the interchange of thought and ideas among photographers actuated by a common impulse of mutual improvement, meeting together socially at home, as well as once or twice a year at conventions. I think at our conventions that it would be well for us to go more in groups up and down the line of the exhibits for general discussion instead of alone or with one another.

DEVELOPMENT PAPERS AND DESENSITISERS.

(A paper read before the Royal Photographic Society).

THE theory of the action of desensitisers on the photographic emulsion has been dealt with by Sheppard and Mees in their "Theory of the Photographic Process." These notes do not, however, deal with the *general* action of desensitisers on emulsions, but rather with the troubles due to *localised* occurrences of desensitisers in photographic raw papers and baryta coating.

Unfortunately, owing to war conditions, these occurrences have been of a very serious nature during the last three or four years. When one considers that the allied paper mills, whose products enjoyed an enviable reputation for freedom from desensitisers in pre-war days, are not now able to produce the same high standard of quality—it is hardly to be wondered at that our British manufacturers have not yet succeeded in producing a perfect base.

In many respects they have given us an excellent substitute for German products, and one can say they have creditably met many of the numerous requirements as to physical and chemical properties, such as dry strength, wet strength, curl, expansion when wet, freedom from blisters, smooth surface, etc. In the matter of desensitisers in the raw base, they have not so far been quite so successful.

Sheppard and Mees give the following ratios for the desensitising action of metals:—

Copper	3.6
Uranium	4.4
Ferric iron	69.0
Mercury (mercuric)	greater than 100.0

It must be remembered that these figures apply only to the particular plate used in these tests because, rather fortunately, emulsions vary greatly in their behaviour to these desensitising substances.

Of the four metals given by Sheppard and Mees, the only ones likely to occur in practice are copper and iron. Taking copper first, it will be seen that the desensitising action of this metal is only 3.6, and in actual practice the occurrence of copper compared to that of iron is very small. When it does occur, it is chiefly from the beater bars of the paper-making machinery or from the defective sorting of the rags. Nowadays its occurrence is rare, as naturally the makers have these two points under their control and obviate it. In cases, however, where it does occur, the following notes from a paper by Mr. Strachan on "Dendritic Growths on

Paper," read before the Royal Microscopical Society, are worthy of note. In it he states that the particle of bronze is attacked by chemical residues in the paper—chief among which is sulphate of alumina with formation of soluble sulphate of copper.

The latter creeps along the fibres of the paper in solution and the final result in the case of dendritic growths is the occurrence in the paper of fibres impregnated with basic copper sulphate.

The interesting point is the way in which the soluble copper salt creeps along the paper fibre, and in the case of a photographic base paper, this spreading, both in the case of copper and iron, produces a desensitised spot of very visible dimensions from an extremely small first cause. It is, however, iron which causes the most trouble in base papers.

From the ratio figures previously given it will be seen that its desensitising action is very high indeed, being 69 against 3.6 for copper, or nearly twenty times as great. As to its occurrence—anyone who has had occasion to test materials for iron will agree that it is difficult *not* to find it.

The dust in any large town contains sufficient to make it necessary to adopt pretty nearly bacteriological precautions as regards dust in order to obtain reliable and concordant results.

The usual method of testing for iron is to either immerse the paper in, or swab it over with, cotton-wool soaked in dilute potassium ferrocyanide and nitric acid—by this means the iron is converted into a ferric salt which gives a deep blue spot, due to the formation of Prussian blue. It is, perhaps, preferable to use the "swab" method, as by this means dust on the surface of the paper is removed, and only iron actually embedded in the paper is made evident.

A further method is to use ferricyanide of potassium and hydrochloric acid under the same conditions as previously, *i.e.*, with a swab, and although this test is one for ferrous iron, whilst it is ferric iron which has the greatest desensitising effect, yet one never meets a case in which the reaction cannot be obtained, and in testing under the microscope in the case of desensitised spots on prints this method is most useful. It, of course, immediately bleaches the black silver image and renders the detection of the particles of iron quite easy.

The most delicate test, and one which very few papers will stand, is to use an acid hydroquinone developer, such as is used for the

development of P.O.P., and to add to it a few drops of silver nitrate, for instance;—

Hydroquinone...	16 grs.
Citric acid	40 grs.
Sodium acetate	1 oz.
Water	20 oz.

This is the stock solution, and when testing, a few drops of 10 per cent. silver nitrate is added just before use. When using the solution, however, the utmost care must be taken, as this test is so delicate that touching the paper with the finger will often cause a black impression to develop.

In testing papers for spots, a microscope of the type used for the examination of half-tone prints, such as that supplied by Beck, is most useful. The sheet of paper is laid on a sheet of plate glass and the long projecting arm of the microscope allows of the easy examination of the whole of the surface. A miniature electric light bulb is arranged to throw a beam of light on the object, and if attached to the arm of the microscope keeps the portion of paper being examined well illuminated, even if the arm is swung about.

Although in many cases the spot resulting from the densitiser is fairly large, the cause of the trouble is extremely small, and is usually well embedded in the paper base, but with a microscope of the type described fitted with a $\frac{1}{2}$ -in. objective—a silver or platinum needle—together with a drop of ferricyanide and hydrochloric acid, there is very little difficulty in getting at the cause of the trouble.

The method of testing raw paper for metallic spots advocated by Valenta, is to soak the paper for about five minutes in from 5 to 6 per cent. acetic acid, and then dry. Then re-soak the sheet in from 3 to 5 per cent. potassium ferrocyanide, and again dry.

The iron spots assume a blue colour due to Prussian blue, whilst the copper spots are a brown colour due to the formation of ferrocyanide of copper.

This method, however, with the intermediate drying, is nothing like so convenient as the use of ferrocyanide and nitric acid, which is the standard method adopted by many paper-makers in testing their raw materials.

The same methods as regards detection are used in the case of spots occurring in the baryta coating, or in the emulsion itself, but the conditions under which the last two are manufactured are much more under control, and spots due to them are of rare occurrence.

In a photographic paper, the baryta coating serves two purposes: the first and most important of which is to effectively insulate the emulsion from any deleterious impurities in the raw base; the second purpose being to modify the shade and surface to suit particular tastes.

In endeavouring to produce with British materials a photographic sensitive paper equal to pre-war productions, it is evident that manufacturers have had to utilise to the full the insulating properties of the baryta coating and to produce a baryta coating which will resist to the greatest extent the "creeping" action of the iron and copper salts present as impurities in the raw paper.

Fortunately, in the case of development papers, it is not necessary to consider the reverse action—that is, the creep of the soluble silver salts into the paper as is the case in printing-out papers. Even when the utmost precautions have been taken with the baryta coating, the creep of the densitiser is not entirely prevented, and such a minute quantity of iron can produce such a disastrous effect, that it is necessary to take any possible steps to prevent this effect. The problem is not so difficult as it is in the case of a plate.

As pointed out by Sheppard and Mees, the action of a densitiser may be described as catalytic, so that a very small amount of the densitiser is able to continually destroy the latent image if given

sufficient time to effect oxidation. In fact, if left for several hours in contact with the densitiser, the latent image is entirely destroyed.

This length of time, *i.e.*, several hours, may easily occur between the exposure and development of a plate, but in the case of paper, development practically always occurs immediately after exposure, so that the catalytic effect is at a minimum and the decrease in density round the spot or impurity is that due to the immediate oxidising effect of the densitiser present.

As stated previously, the decrease in sensitiveness, due to a definite quantity of iron in contact with the emulsion, is not constant, but varies according to the particular type of emulsion, being different for an acid as against an ammonia emulsion, and also varying with different proportions of the three halogens, chlorine, bromine, and iodine present, so that one can use an emulsion which is affected as little as possible by densitisers.

In addition there still remains the possibility of the use of a negative catalyst, such as mannite, quinone or oxalates, to re-sensitise the emulsion.

Although the amount of negative catalyst required is large in proportion to the densitiser, because one must provide at any and every point a sufficient quantity to deal with the maximum densitising effect, yet by careful attention to the following points:—

- (1) The insulating properties of the baryta coating;
 - (2) The choice of an emulsion as little as possible subject to densitisers;
 - (3) Compensation of the densitiser by a negative catalyst;
- it is impossible to produce a development paper on a base containing so many metallic impurities as to be quite impossible for direct coating with emulsion.

The tests which I have for your inspection are intended to show the practical application of the points just enumerated, and may be classified as follows:—

- (1) Raw paper tested with ferrocyanide and nitric acid showing the numerous iron spots in the base.
- (2) Normal emulsion coated on the above base, showing the numerous densitised spots due to the iron.
- (3) The perfectly even density obtainable with this base when due precautions are observed.
- (4) Sheets showing even density with one-half treated with ferrocyanide and hydrochloric acid to bleach it. These sheets show that in the particular examples there are numerous iron spots in the base and are a further proof that a perfectly even density has been obtained on a base containing a tremendous amount of densitiser.

I am glad to say that the quality of the raw base now being produced is a distinct advance on the samples shown, but in order to show the value of the methods indicated it was advisable to give examples showing their action under adverse conditions.

Still, for the production of a development paper as near perfection as possible, it is undoubtedly an asset to be able to make it as resistant as possible to the effects of impurities in the base.

As you are aware, in pre-war days an immense amount of photographic base was imported from Germany, and although up to the present our manufacturers have not quite succeeded in giving us a substitute equally pure, I feel sure that now they are in a position to tackle the problem, by methods unattainable during the war, they will soon reach the required standard, and enable us to produce a development paper which will be British throughout, equal to the pre-war standard as regards the raw base, and, if possible, a little better because we can give added resistance to defects.

WALTER C. MANN.

MESSRS. ILFORD, LIMITED, advise us that the new booklet on "Panchromatism," which deals with certain of their exhibits at the Scientific Products Exhibition, is now in the press, and will be sent on application to any address post free 9d. Those interested in the display of panchromatic results and appliances are at the same time reminded that the Scientific Products Exhibition closes on August 5.

UNOFFICIAL WAR PHOTOGRAPHS.—The Committee of the Imperial War Museum desire to complete their collection of photographs and scenes of historical interest, and invite officers and other ranks who have unofficial photographs of such scenes to communicate with the Keeper of Photographs, Imperial War Museum, 10, Coventry Street, W.1. Prints, with description and titles, should be forwarded for inspection.

THE PHOTOGRAPHIC CORRECTION OF NEGATIVES TAKEN OBLIQUELY.

[For the purposes of the French Army Aviation Service, in which he was engaged during the greater part of the war, M. L. P. Clerc has investigated with great thoroughness the mathematical conditions involved in transforming a photograph taken from an inclined aerial camera into one corresponding with that obtained from the same view-point, but with the lens-axis vertical. His study has led him to the design of a purely automatic camera carrying out this "redressement." Inasmuch as aerial photographic mapping promises to be an important peace-time application of photography we publish a translation of the text of his paper.—EDS. "B.J."]

(Continued from page 413.)

The image corrected without deformation being similar to the image which would have been obtained directly from the same view-point S on a horizontal plate, we can arrange this image in the bundle of rays from S so that each point of this image shall be on the ray coming from the corresponding point of the terrestrial subject, and it is seen that in the image thus placed the rôle of principal point is played by V', and that of the principal distance or equivalent focal length by the length S P'.

The position of the point V' in the corrected image can be easily determined by drawing from P' (defined by the intersection of the axes of the image) on a line corresponding to the line of greatest inclination—i.e., drawing a segment P'V'.

$$P'V' = SP' \cos \omega = SP' \sin \omega = n_P SP \sin \omega = n_P F \sin \omega$$

$$P'V' = \frac{f \sin^2 \omega}{\sin \alpha \cos \omega} = NH \tan \omega.$$

The equivalent focal length HSV' is given by

$$F' = \frac{P'V'}{\tan \omega} = NH \text{ or } F' = SP' \cos \omega = n_P F \cos \omega = \frac{f \sin \omega}{\sin \alpha}$$

$$F' = \frac{F \sin \beta}{\sin \alpha}$$

and it is seen that the enlargement of the corrected image relatively to the image photographed from the same point with the same lens on to a horizontal plate is

$$n_P \cos \omega = \frac{m \sin \omega}{\sin \alpha} = \frac{\sin \beta}{\sin \alpha}$$

We may find the limit of the angle ω for which the vanishing point of the verticals V is included in the effective area of the negative, the camera being assumed to have no sideway inclination in the right-angled triangle SPV (fig. 10)

$$PV = F \tan \omega$$

In the case of a 13 x 18 c.m. camera, with 26 c.m. lens, the limits of PV and the corresponding values of ω are:—

Camera, central lens, "LT 1915 type," PV < .06 metre ω < 13°

Camera, decentered lens, "1914 type," PV < .09 metre ω < 19°

In the case of panoramic photographs to be corrected to the vertical, the condition of having in the field the principal point of the corrected image, i.e., the point H', the image of the principal point of the horizon H, leads to the same values of the angle ω , the obliquity of the axis being then measured not to the vertical but to the horizontal plane.

It will thus be seen that in all cases of oblique photography there is an advantage, as regards good utilisation of the corrected image, in the use of cameras in which the lens is decentered from above downwards, the use of too oblique pencils being thus avoided.

II. SPECIAL CASES.

§ 12. *The Principal Point of the Negative is kept on the Optical Axis.*—In certain cases it may be of advantage to avoid the somewhat delicate adjustment of decentering by taking steps to keep the principal central point of the negative on the optical axis of the correcting lens.

The conditions [A] and [C] worked out for the general case then apply without alteration, but condition (B), since $d = 0$, becomes

$$\cos \beta = \cos \alpha \cos \omega$$

but it is preferable to substitute for this latter the condition

$$\sin \alpha = \frac{m}{n} \tan \omega \tag{B'}$$

obtained by making $d = 0$ in the equation [2] of paragraph 4.

Lastly, the condition [D] becomes identical with the condition [B'] above: in the special case under consideration the enlargement n on the optical axis becomes the same as the enlargement n_P of the principal horizontal, and, therefore, the equivalent focal distance of the corrected image is

$$F' = NH = n F \cos \omega$$

a value which, by introduction into equation [D], renders this latter identical with [B'].

The equation [C] of non-deformation, in this special case, can be expressed in another form, better adapted to the discussion of conditions of possibility. For this purpose we eliminate from this equation and from [A] and [B] either α and ω , or α and β , or β and ω .

Taking, as already done in paragraph 5,

$$k = \frac{S H}{O H} = \frac{\sin \beta}{m \sin \omega}$$

we obtain after elimination and simplification⁷

$$k = \sqrt{1 + \tan^2 \beta \left(\frac{1}{n^2} + \frac{1}{m} \right)} = \sqrt{\frac{1 + \tan^2 \omega}{1 + m^2 \tan^2 \omega \left(1 - \frac{1}{n^2} \right)}}$$

$$= \sqrt{\frac{m^2 + (m^2 + n^2) \tan^2 \alpha}{m^2 (1 + n^2 \tan^2 \alpha)}}$$

whence it is seen that the necessary condition that $k = 1$ is

$$\frac{1}{n^2} + \frac{1}{m^2} = 1 \tag{C'}$$

This condition necessarily implies

$$n > 1 \text{ and } m > 1$$

Thus, when the principal horizontal of the negative is brought on to the optical axis, correction without deformation is possible only by enlarging and by using a lens of focal length greater than that of the taking lens.

For each value of m , determined by the choice of the correcting lens, there is a corresponding value of the enlargement n such that

$$n = \frac{m}{\sqrt{m^2 - 1}}$$

A curve (fig. 11) can be constructed in accordance with this relation, and the required value of n readily ascertained for any given value of m .

⁷ We will confine ourselves to carrying out the calculation in the single case where the angle α and ω are eliminated. The relations between the trigonometric lines of the same arc, viz.:—

$$\sin^2 \omega = \frac{\tan^2 \omega}{1 + \tan^2 \omega}, \quad \alpha = \sin^2 \beta =$$

allow us to write the condition (B') as:—

$$\sin^2 \omega = \frac{\frac{n^2 \sin^2 \alpha}{m^2}}{1 + \frac{n^2 \sin^2 \alpha}{m^2}} = \frac{\frac{n^2 \tan^2 \alpha}{m^2 (1 + \tan^2 \alpha)}}{m^2 + n^2 \frac{\tan^2 \alpha}{1 + \tan^2 \alpha}}$$

If now the values of $\sin \omega$ and $\sin \beta$ are inserted into the expression for k , we have

$$k^2 = \frac{\frac{\tan^2 \beta}{1 + \tan^2 \beta}}{\frac{n^2 \frac{\tan^2 \alpha}{m^2 (1 + \tan^2 \alpha)}}{m^2 + n^2 \frac{\tan^2 \alpha}{1 + \tan^2 \alpha}}} = \frac{\frac{\tan^2 \beta}{1 + \tan^2 \beta} \left(m^2 + n^2 \frac{\tan^2 \alpha}{1 + \tan^2 \alpha} \right)}{m^2 n^2 \frac{\tan^2 \alpha}{1 + \tan^2 \alpha}}$$

Lastly, expression $\tan \alpha$ in terms of $\tan \beta$ according to equation (A)

$$k^2 = \frac{\tan^2 \beta [m^2 (n^2 + \tan^2 \beta) + n^2 \tan^2 \beta]}{m^2 n^2 \tan^2 \beta (1 + \tan^2 \beta)} = \frac{1 + \tan^2 \beta \left(\frac{1}{n^2} + \frac{1}{m} \right)}{1 + \tan^2 \beta}$$

For a given value of the enlargement n measured along the optical axis the total length PP' of the correction camera is given by

$$L = \left(2 + n + \frac{1}{n}\right)f$$

Substituting for f its value mF and for n its value from equation [1] we obtain

$$L = \left(2 + \frac{m}{\sqrt{m^2 - 1}} + \frac{\sqrt{m^2 - 1}}{m}\right)mF$$

$$= F \frac{m \sqrt{m^2 - 1} + m^2 + (m^2 - 1)}{\sqrt{m^2 - 1}}$$

$$L = F \frac{(m + \sqrt{m^2 - 1})^2}{\sqrt{m^2 - 1}}$$

Fig. 11.

In constructing the curve (fig. 12), which gives the different values of $L:F$ in terms of m , it is seen that this curve exhibits a very marked minimum for the value of m equal to $\frac{2}{3}$ with which correspond the values

$$m = 1.154 \quad L = 5.194F \quad n = 2.006$$

Fig. 12.

When the correction camera is intended for the rectification of negatives made with taking cameras fitted with lens of focal length F , it is advisable, as a means of reducing the bulk of the correction camera, to select a lens of focal length f (and of corresponding value of m) such that L is a minimum.

Among the regular cameras of the French Army Aviation Service, that which by the extent of its field is best adapted for cartographic work is the so-called 0.26, in which the focal length is between 25 and 27 cm.

In adopting for the correction camera a lens of focal length $0.26 \times 1.154 = 0.300$ metre (30 cm.) the minimum length of the correcting camera will be $L = 5.194 \times 0.26 = 1.350$ metre.

In the case where the focal length of the lens of the taking camera exceeds one of the limiting values, the values of m , n and L would become

$$F = 0.25 \quad m = \frac{.30}{.25} = 1.2 \quad n = 1.83 \quad L = 1.36 \text{ metres}$$

$$F = 0.27 \quad m = \frac{.30}{.27} = 1.1 \quad n = 2.33 \quad L = 1.45 \text{ ,,}$$

Under these conditions correction without deformation is assured by the use of a correcting camera of extension, such as to permit of a variation of enlargement n within the limits 1.75 to 2.45.

A greater range can, however, be of service for the purpose of subsequently bringing the corrected image to any required scale.

As in the general case, the condition [B] allows of fixing the limiting values of the angle ω corresponding to the practical limiting values imposed on β . Taking 30° as a maximum for β , the limiting values of the angle ω corresponding with different values of m previously contemplated are:—

m	1.1	1.175	1.2
ω	27°	25°	24.3°

In the case where the principal point of the horizon is kept on the optical axis, the angles α and β can be constructed graphically (fig. 13). On the optical axis OF , O being the optical centre and F the rear focus of the correction camera, draw a perpendicular at F , and with O as centre describe an arc of a circle of radius $OH = F \sin \omega$, which determines the point H . From this point describe

Fig. 13.

the arc of a circle of radius $HP = F \cot \omega$, which fixes the position of P on OF produced.

§13. *Enlargement on the Axis is Constant and Equal to Unity.*—When $n = 1$, the conditions worked out for the general case become

$$\tan \alpha = \tan \beta \text{ whence } \alpha = \beta$$

$$e \frac{d}{\cos \alpha} = F \frac{\cos \alpha (1 - \cos \omega)}{\sin \omega \cos \alpha} = F \frac{1 - \cos \omega}{\sin \omega} = F \tan \frac{\omega}{2}$$

$$\sin \alpha = m \sin \omega$$

$$F' = NH = f \frac{\sin \omega}{\sin \alpha} = f \frac{\sin \omega}{m \sin \omega} = \frac{f}{m} = F$$

It is thus seen that in these conditions the system is constantly symmetrical in respect to the plane, perpendicular to the optical axis, in which is the optical centre, whence result certain facilities for the automatic operation (in conjunction) of the two rocking frames. In this case also it is to be noted that the corrected image is on the same scale as that which would have been photographed directly from the same view-point with the same lens on a horizontal plate (or on a vertical plate in the case of correction of an image taken on an, approximately, vertical plate).

Moreover, if $m = 1$, that is to say if we employ for the correction camera the lens used on the taking camera or a lens of the same focal length, the conditions of adjustment become

$$\sin \alpha = \sin \omega, \text{ whence } \alpha = \beta = \omega$$

$$d = F \frac{1 - \cos \omega}{\tan \omega} \text{ or } e = F \frac{1 - \cos \omega}{\sin \omega} = F \tan \frac{\omega}{2}$$

The decentering would then depend on a single parameter, the angle ω which is at the same time the angle of the recking frame, and it is then possible to operate the movements of tilting and decentering in a strictly mechanical way by means of a suitably formed cam.

We could bring within the scope of this last method the correction of negatives taken with a lens of any focal length, longer or shorter than that of the correction lens, by making the corrected negative not from a contact transparency of the original negative, but from a transparency reduced or enlarged upon a scale m , such that it is identical with one made with a lens of equivalent focal length equal to that of the correcting lens.

§ 14. *Correction Lens has the Same Focal Length as Taking Lens.*—By making $m = 1$, the conditions of correction become

$$\sin \beta = \sin \omega, \text{ whence } \beta = \omega$$

$$\tan \omega = n \tan \alpha$$

$$d = F \frac{1 - \cos \alpha}{\tan \omega} = F' \frac{1 - \cos \alpha}{n \tan \alpha} \text{ or } e = F' \frac{1 - \cos \alpha}{n \sin \alpha} = \frac{F}{n} \tan \frac{\alpha}{2}$$

$$\sin \alpha = \frac{F}{F'} \sin \omega$$

If also $n = 1$, the case becomes that studied in the preceding paragraph.

We could also, by the same artifice of previous change of the scale, carry out the correction without decentering. This would be done by making a positive transparency reduced to the scale of $1/m$, and then correcting by enlarging on the scale n , such that

$$\frac{1}{m^2} + \frac{1}{n^2} = 1$$

The ratio n/m being thus susceptible of being chosen arbitrarily, we could adopt for it a value such that we can arrange as we like the scale of the corrected photograph. Denoting, as already done, the equivalent focal length of the correction camera-lens by F' and the focal length of the taking lens as F/m , we have

$$\frac{n}{m} = \frac{F'}{F \cos \omega}$$

(To be continued.)

COMPLETE SPECIFICATIONS ACCEPTED,

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

TRIPLET LARGE-APERTURE LENSES.—No. 127,058 (April 19, 1917).

The invention relates to optical lens combinations comprising compound or achromatic lenses, whereby spherical aberration is more or less avoided, thereby obtaining a lens suitable for use in microscopes, telescopes, and chiefly for photographic purposes. The main object is to obtain a very large aperture relatively to the equivalent focal length consistently with either total freedom from spherical aberration, or else a normal degree of spherical aberration whether over or under corrected.

It is found that a triple combination consisting of one double convex positive lens of low refractive index enclosed between and optically united to or cemented to two meniscus negative lenses of very high refractive index and approximately equal power gives a more perfect uniformity in its spherical aberration correction throughout its aperture than any other combination, so that a clear working aperture equal to at least one-third of the equivalent focal length is easily obtainable consistently with perfect correction for spherical aberration, that is, the spherical aberration of the third order is practically eliminated. For instance, the following combination may be cited:—

Crown glass refractive index for D-ray = 1.5216

Reciprocal value of dispersive power (C to F) = 50 to 51

Flint lenses refractive index for D-ray = 1.694

Reciprocal value of dispersive power for D-ray (C to F) = 31

Radii of curves in the order that the light passes through them

+ means convex.

− sign means concave.

$$\begin{array}{ccc} L_1 & L_2 & L_3 \\ + 2.5 - 1.25 & + 1.25 + 1.095 & - 1.095 + 1.94 \\ t_1 = .125 & t_2 = .32 & t_3 = .125 \end{array}$$

where t is thickness of lens.

Diameter (D) = 1.10 inch, equivalent focal length = 3.01 inch.

These lenses, when cemented together, yield an achromatic objective which is free from spherical aberration for a pencil of rays diverging from a point on the axis about 11 ins. away from the first surface.

The curves can also be arranged for giving perfect correction against spherical aberration when the first surface is presented to parallel rays. In such a form the combination may be advantageously used for the objective of a Galilean telescope wherein a large relative aperture is necessary for securing a large field of view. It is also obvious that two such triple lenses can be placed near together in the same axis for forming a still more powerful combination whose aperture will be nearly two-thirds of its equivalent focal length, a combination highly desirable for rapid photography or for cinematograph projection.

It then becomes important to introduce such modifications to the curves so that a fairly flat image is produced. If this is done in the triple objectives themselves, then it is well known that all that can be done is to secure that the image of a series of circles concentric with the axis shall be flat, while the image simultaneously formed of radial lines passing through the axis will remain curved concave to the lenses and approximately to a radius equal to $2\frac{1}{2}$ times the equivalent focal length.

But it is very questionable whether this condition can be fulfilled without resorting to an impracticably large separation between the two triple positive lenses.

Should it be necessary to get the latter image flat as well as the former, then a further auxiliary device is used, which consists in placing a negative correcting lens in, or almost in, the plane of the image formed by the above positive combination, and having its principal focal length about equal to that of the positive combination above described. If this correcting lens be concavo-plane, the real image should be formed on or just beyond its second or plane surface, where the photographic plate should be placed to receive the image.

It can be shown that if a flat and anastigmatic image be thrown by any positive lens on the left into the above negative lens on the right in the manner described, then the negative lens will impress upon it an anastigmatic curvature, and will convert it from a flat anastigmatic image into a curved anastigmatic image whose radius of curvature is n times the principal focal length of the negative lens and curved concave towards the right or convex towards the positive combination on the left. The above term n denotes the refractive index of the negative lens.

It can then be arranged for the positive combination of one or two triples to be so corrected as to yield a curved anastigmatic image whose radius of curvature will also be roughly about 1.4 to 1.5 times the combined focal length of the positive combination and curved concave to the latter. If the negative lenses in the focal plane is of about equal power to the positive combination, then it follows that the curvatures of the two images yielded by the positive projecting lens and the negative corrector lens in the

focus on the other hand will neutralise each other, resulting in a flat and also anastigmatic final image or field of view.

The shape of the negative lens, while only slightly affecting this relationship, can at the same time be so arranged as to give no distortion or departure from rectilinearity of the images of straight lines. Thus, if it be a simple negative lens having a refractive index of 1.5, then the radius of curvature of the

second concave surface should be four times that of the first concave surface.

Should the negative corrector lens be concavo-plane, then it will give slight positive distortion of straight lines, amounting to about 2 per cent. at a distance from the axis equal to one-fourth of its focal length.

The following are the glasses, curves, and other data for a flat-field anastigmatic lens of an aperture equal to about half of its equivalent focal length, which is about 2.21 ins. The combination is shown in the accompanying drawing:—

Lenses l_1 and l_2 are of dense barium crown glass having

$$N_D = 1.6237 \text{ and } \frac{N_D - 1}{N_F - N_C} = 44.9$$

Lenses l_3 and l_4 are of highly dispersive crown glass having

$$N_D = 1.5216 \text{ and } \frac{N_D - 1}{N_F - N_C} = 51.1$$

Lenses l_5 and l_6 are of extra dense flint glass having

$$N_D = 1.694 \text{ and } \frac{N_D - 1}{N_F - N_C} = 31.0$$

The - signs indicate concave surfaces.

RADII OF CURVES.

}	L_1	l_2	$r_1 - 1.30$	Central thickness = .07
			$r_2 - .7725$	
			$r_3 + .7725$	Central thickness = .385
			$r_4 + 1.65$	
}	L_2	l_5	$r_5 - 1.65$	Central thickness = .08
			$r_6 + 9.8$	
			Finished diameters = 1.13	
			D	
}	L_3	l_6	$r_1 + 1.339$	Central thickness = .08
			$r_2 - .802$	
			$r_3 + .802$	Central thickness = .385
			$r_4 + 1.49$	
}	L_4	l_6	$r_5 - 1.49$	Central thickness = .08
			$r_6 + 8.75$	
			Finished diameter = .13.	

Negative corrector lens of 1.37" focal length of fluor crown glass having $N_D = 1.4785$. In order to fulfil the Petzval condition it is desirable to employ a glass of low refraction for the negative corrector lens.

$$L_0 \left\{ \begin{array}{l} \text{Curves } r_1 = -1.00 \text{ in.} \\ \text{Radii } r_2 = -1.925 \text{ in.} \end{array} \right. \begin{array}{l} \text{Central thickness} = .03 \\ \text{Finished diameter } 1.20 \text{ in.} \\ \text{Clear aperture of 2nd surface} = 1.15. \end{array}$$

This combination yields a flat and almost anastigmatic image over a field of 20 degs. diameter.

When assembling this lens, it must be remembered that the focal plane for distant objects lies in the plane of the back edge of the second surface of the corrector lens, which is left of 1.15 ins. diameter across edges of polished surface.

For a focussing screen a disc of parallel flat glass greyed on one side should therefore be placed with its greyed surface up in contact with the back edge of the corrector lens, and the two compound lenses L_1 and L_2 be adjusted to project the image sharply upon this focussing screen. Then, if desired, the screen can be removed and the images of a distant point of light can then be observed through a powerful achromatic magnifier of at most .25 focal length and .125 aperture, used as an eyepiece.

The image when thrown near the edge of the negative corrector should be examined for coma. If there is marked inward coma, then L_1 and L_2 want screwing nearer together. If there is outward coma, L_1 and L_2 want screwing further apart.

It may be that glasses cannot be obtained very exactly to the above specification, and therefore the results deviate somewhat from the normal.

The spherical aberration of L_1 used alone and when focussing an image of a distant point of light should be fairly well corrected, showing a tendency to a slight zone of aberration, the rays about half way between centre and edge having the shortest focus. If it appears over-corrected for aberration, then the first radius may be deepened with advantage; but this will produce a little inward coma at the foci of oblique rays, and L_1 and L_2 will have to be brought nearer together. This will slightly shorten the axial focal length.

Although the axial focal image of a distant point of light formed by this lens at aperture $1/2$ cannot be said to be entirely free from a zone of aberration, yet it is a mere fraction of what is found at the axial focus of a petzval portrait lens or any other lens having anything approaching the large relative aperture in question.

It is also quite possible to employ one compound positive lens substantially like the L_1 above specified, which is characterised by a large amount of inward coma and place a stop behind it at a distance equal to about a quarter or one-third of its focal length, which, by its selective effect, may cause the image projected by L_1 to be fairly anastigmatic, and this image may be projected to the rear side of a negative corrector lens of a focal length approximately equal to that of the said positive lens, and by whose action the curved anastigmatic image may be flattened; but this method does not admit of so large a relative aperture. Alfred Taylor, of Messrs. T. Cooke and Sons, Limited, Buckingham Works, Bishop-hill, York, and Harold Dennis Taylor, Buckingham Works, Bishop-hill, York.

APPLICATIONS FOR REGISTRATION.

KINEPARTS.—No. 386,864. Cinematograph apparatus. Thomas Linforth Jones, 10, Ham Yard, London, W.1; cinematograph and general instrument maker and repairer. December 14, 1918.

FORTHCOMING EXHIBITIONS.

September 13 to October 11.—London Salon of Photography. Entries close September 2. Hon. sec., 5a, Pall Mall East, London, S.W.1.

October 13 to November 29.—Royal Photographic Society. Secretary, J. McIntosh, 35, Russell Square, W.C.1.

SOLDIERS' PHOTOGRAPHS OF THE KING AND QUEEN.—During one of the intervals in the procession on Saturday last, July 19, an Australian soldier stepped out from the crowd near the Royal Pavilion and prepared to take a photograph of the King and Queen. Their Majesties (reports the "Times") noticed the soldier's preparations, and smilingly stood while the photograph was taken. With a salute the soldier stepped back. Prompted by his success other soldiers with cameras and several civilian amateur photographers to the number of between twenty and thirty also came forward, and again their Majesties acquiesced.

TUESDAY, JULY 29.

Hackney Photographic Society. "Mounting Prints." By Four Members.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the Council was held on Friday, July 11, 1919. Present: Messrs. Basil, Chapman, Gordon Chase, Corbett, Dickinson, Ellis, Fry, Gray, Haines, Speaight, and Wakefield (London members), and Marcus Adams (Reading), Beaufort (Birmingham), Chidley (Chester), Illingworth (Northampton), Read (Southport), Spink (Brighton), and Turner (Hull).

The minutes of the previous meeting were read and confirmed.

The Hon. Sec. reported that he had received an average number of business communications from members during the month, and that most of them had been dealt with by return of post; the remainder after consultation. A member had sought the opinion of the Council in regard to his charges for attending (time taken 12½ hours), making three whole-plate negatives at a factory under difficult circumstances, supplying twenty-four mounted prints, and delivering the negatives. His charge was six guineas, and exception had been taken to it. The Council took the view that the charges were reasonable, and instructed the Hon. Sec. to write the member to that effect.

Another inquiry was put by a member, viz.: "A professional photographer is asked to attend and photograph a wedding group. The local illustrated paper also asks permission to attend and photograph for their paper. Can the professional photographer complain if the paper sends proofs and canvasses for orders?"

Mr. Turner stated that a great amount of this kind of business arose in country areas, and that an agreement was generally made between the newspapers and the professional photographer on the following lines:—The photographer to supply a photograph for publication in the paper (with or without charge), the photographer's name appearing under the illustration. The newspaper thus obtains its photograph with licence to reproduce in one issue only without having to incur the expense of sending an operator; the photographer obtains an advertisement, and retains his interest in the purely photographic part of the business. The Hon. Sec. was instructed to write the member to this effect.

Complaint was received from a member that a local schoolmaster, an amateur, was attending public and semi-public functions nominally for press purposes, subsequently supplying photographs at very cheap rates. This practice was commenced when the member and other professional photographers in the same town were on war service, and was being continued to their great annoyance and loss now that they had returned to their business occupations. The Hon. Sec. was instructed to obtain further information as to the status of the schoolmaster, and to ascertain who were his employers.

Complaint was received from a member who stated that a firm of dealers had refused to continue to supply certain goods on "dealers' terms." The matter had been investigated, and it was obvious that the member had a claim either for a continuation of the old terms, or for a credit for his unsold stock. The council authorised the continuation of the negotiations so as to secure the best possible arrangement for the member in question. One of the difficulties in the matter was that dealers and manufacturers had no stock of the kind required which could be supplied. The Hon. Sec. stated that he had little doubt but that the dealing firm in question would settle the matter quite equitably with their member.

The Hon. Sec. reported that a new edition of the Handbook, with added matter of a useful character, and revised and brought up to

date by Mr. Mackie, was being prepared, and would be ready for issue towards the end of the year.

Mr. Read proposed that all nominations of new members should come before the Council for election. It was pointed out that, as the Council meetings were held at intervals of one month, this suggestion would involve considerable delay, which might easily prejudice the Association. It was further argued that a professional photographer, who came within the four corners of the membership rule, had practically an inherent right to become a member, and that any possible veto, possessed by the Council under Rule 4, was on the ground of eligibility only.

The matter of the incorporation of the P.P.A. was further adjourned, in order that opportunity might be given for ascertaining the full import of the advantages claimed for the proposed action. Two members of the Council were specially instructed to inquire, and, if possible, ascertain the effect of incorporation upon future official relations of the Association with Government Departments. The matter of the Association's financial position was discussed intimately, and the general effect likely to be caused by a change in the legal status of the Association considered in its several aspects. Some other matters dependent upon this decision were also adjourned.

The Hon. Sec. was authorised to join the Industrial Reconstruction Council.

Mr. Chidley reported that he had investigated on the spot the complaint of one member that another, practising professional photography in the same town, was showing specimens which were not his own work. Mr. Chidley stated that the photographer was personally known to himself and Mr. Illingworth, and he was quite satisfied that the specimens were being properly exhibited. Some of them were made when the photographer whose action was complained about was in the service of an employer, and a letter from that employer was shown to Mr. Chidley authorising the use of the photographs. The Council, therefore, found themselves in the happy position of being able to reassure both the members in question.

It was reported that certain firms undertook to supply specimens for photographers who were newly entering the profession, and this practice the Council considered to be reprehensible and quite unprofessional. The Hon. Sec. was instructed to get such information as he could and report upon the matter to the next meeting of Council, which was fixed for the second Friday (10th) in October, the recess intervening.

CROYDON CAMERA CLUB.

DR. F. KNOTT read a most thoughtful paper on "Memory Systems, Past and Present," with agreeable succinctness, clearly describing the evolution of artificial aids to memory, so much advertised in recent times, but unhappily never adopted by the not uncommon individual who so frequently finds himself divorced from loose cash, and regards his suffering friends as a happy media for reunion.

Granted that many things occur in life for which a system compelling forgetfulness would be extremely useful, yet what is more aggravating than to endeavour vainly to recall some familiar name, or, perhaps, fact, which has stuck in the sub-consciousness and refuses to traverse the mysterious connecting link with the consciousness. Again, think of the value of any system which would allow one to store mentally such charming articles as "The Photographic Correction of Negatives Taken Obliquely," which recently appeared in the "B.J.," and dish them up from memory in the future for the edification of astounded friends. And this quite apart from the £.s.d. point of view, which, according to the advertisements, is highly attractive, not to mention the potential acquirement of high office in many directions.

The lecturer just gave an outline of the various systems proposed from time to time, the first being before the Christian era, and then passed on to a detailed examination. On one point he was emphatic, namely, that modern systems are but variations of the old, and possess no essential elements of novelty, despite strong allegations to the contrary. A discussion followed the paper during which the doctor said he had found mnemonics most useful in remembering data. A most cordial vote of thanks was accorded for a lecture which raised many points of real interest.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS.

A very largely attended meeting was held at the office, 39, Blackfriars Street, Manchester, on Tuesday, July 15, 1919. Mr. Fred Kenworthy presiding. A great deal of correspondence having been dealt with, it was decided, after considering applications for membership, to form a sub-committee to deal with all such proposals and to report, after making inquiries into the standing of the photographers of the profession, as it was thought necessary that at this stage of the society's progress it was advisable to consider very carefully all future applications for membership.

A very lengthy discussion took place on the quality of paper being supplied at present by various manufacturers, it being pointed out by several members that the paper was very inferior in quality and caused a great deal of loss to the photographers in consequence. It was the general expression of opinion that during the war there was every excuse for this, and the members considered that the time had arrived for photographers to co-operate together and insist upon a better quality of material being supplied to them. After the matter had been very fully discussed, the secretary was instructed to get in touch with the members of the society and ask them to send in their comments on this very important subject.

It was decided to hold the next meeting at Southport on a date to be arranged later. It was suggested that at this meeting a series of papers should be given by various members.

After other detail work had been dealt with, a vote of thanks was proposed to the chairman, and the business of the meeting terminated.

Commercial & Legal Intelligence.

LOUVRE STUDIOS, LIMITED.—The Official Receiver, in the High Court of Justice, has now issued his report under the liquidation of the Louvre Studios, Limited, of 127, Earl's Court Road, Earl's Court, S.W.5. The gross liabilities as regards creditors amount to £2,301 9s. 3d. The assets consisting of stock-in-trade are returned at £100, thus leaving a deficiency of £2,201 9s. 3d. The paid-up capital of the company is £100, to which has to be added the above deficiency of £2,201 9s. 3d., making the total deficiency £2,301 9s. 3d. The Official Receiver's report upon the case is to the following effect:—The winding-up order was made on March 18, 1919, upon the petition of a creditor. The company was registered on December 22, 1917, as a private company with a nominal capital of £100, divided into ninety-five Ordinary shares and five Preference shares of £1 each. Its objects were to carry on business as photographers, etc. The company was promoted by J. St. L. Stallwood and Miss H. B. Tylour. In March, 1918, it purchased from one, Matthew Kelly, the business of a miniature dealer, carried on by him at 127, Earl's Court Road, known as "The King Edward Studios." The company continued the business at that address, and also carried it on at 171a, Sloane Street, W. The consideration for the purchase was the payment of £400 in cash, the issue of £600 of debentures of the company in twelve debentures of £50 each, and the allotment of twenty-four Ordinary Shares. By the terms of the agreement the debentures and shares were issued to the vendor's nominee, and the vendor further covenanted not to trade as a miniature dealer. The directors of the company were Miss H. B. Tylour, Mrs. M. C. Lang, E. C. Dyer, and Matthew Kelly. Kelly was the only director at the winding-up. Ninety-five ordinary and three preference shares were allotted to Miss H. B. Tylour as fully-paid under an agreement for services rendered. In addition to the £600 of debentures issued as above mentioned, twelve debentures of £50 each, carrying interest at 12½ per cent., were issued to six persons on March 13 and 25, 1918, purporting to be for cash, but on September 6, 1918, owing to the unsatisfactory state of the company, Kelly required greater security, and it was decided that satisfaction for the debentures other than those issued to himself be entered up at Somerset House, the holders to rank as unsecured creditors. On May 2, 1918, Miss Tylour resigned from the managing directorship, and on July 31, 1918, Kelly became managing director. The books of the company have been very imperfectly kept, and the information supplied as to its business affairs is

defective. The failure of the company is attributed by Kelly to mismanagement through a lack of knowledge of the business on the part of the purchasers.

LEIGH MANUFACTURERS' AFFAIRS.—At the offices of the Official Receiver for the Chelmsford District, Bedford Row, W.C., last week, the first meeting of creditors was held under the failure of Peter Morrison, of Henry's Hall, Leigh-on-Sea, and also under the failure of his brother Thomas Morrison, of Henry's Hall, and the Laurels, Chalkwell Park Drive, Leigh-on-Sea.

The statement of affairs filed by Peter Morrison showed gross liabilities amounting to £2,822 11s. 1d., of which £1,122 11s. 1d. was expected to rank against the estate for dividend. The assets consisted of a bad debt of £251 15s., which was estimated to be of no value. The deficiency was returned at £1,122 11s. 1d. The debtor alleged his failure to have been caused through unsuccessful investment in company, and costs of litigation.

The Official Receiver's observations on the case are as follows:—The receiving order was made on the petition of creditors, the act of bankruptcy being the failure of the debtor to comply with the requirements of a bankruptcy notice. The debtor, aged forty-four, stated that he was a solicitor and had carried on business in Castle Street, Edinburgh, until April, 1916. He then had to relinquish his practice owing to ill-health and went to live at Southend-on-Sea.

In or about May, 1915, he, in conjunction with his brother, raised the sum of £350 for the purpose of completing the purchase of the machinery and plant of a photographic paper manufactory at Leigh-on-Sea, which another person had agreed to purchase for £550. Upon the completion of the purchase, he and his brother took possession of the business and carried it on under the name of the Leigh Photographic Paper Co.

In September, 1916, a company was floated under the name of the Leigh Photographic Paper Company, Ltd., and the business was transferred to the company for £4,000, to be satisfied by the allotment of shares to him and his brother or their nominees. The sum of £4,000 was raised on the security of debentures of the company, and the debtor and his brother charged their interest under the will of their father further to secure this sum. In February, 1918, the name of the company was changed to Essex Photographics, Ltd. The business was carried on under the direction of the debtor and others until June, 1918, when a debenture-holder's action was commenced and a receiver was appointed.

Proceedings were taken to recover the lease which was in the name of the gentleman above, and an order was made directing that the lease be transferred to the company upon certain terms, and the debtor and his brother were ordered to pay the costs.

On the debenture-holder's action the Receiver made application to the Court for leave to close the business, which application the debtor opposed, and the Court ordered the business could be kept open if the debtor provided the necessary funds to continue it. For this purpose he, in conjunction with his brother, borrowed £200 from the petitioning creditor, but did not pay the amount to the receiver within the time fixed by the Court, and the business was closed. The money was used in payment of certain accounts. The instalments became in arrear, and these proceedings followed.

The unsecured indebtedness is stated to be due as to £275 damages and costs for wrongful dismissal. As to £200 overdraft at the bank. As to £260 to the petitioning creditor for money lent. As to £100 to a relative for money lent, and as to £37 11s. 1d. for solicitor's costs.

The security held by the creditors scheduled as fully secured consists of the debtor's reversionary interest under the will of his late father and the creditor scheduled as partly secured holds a second charge on the same reversion. The contingent liability is an overdraft on the account of the company at their bank, which was guaranteed by the debtor. The debt due to the estate consists of wages and directors' fees, which at present there is no prospect of recovering.

The debtor is a bachelor and has no household furniture.

The debtor has not been adjudged bankrupt, and states that he is considering making a proposition to the creditors, but no proposal has yet been lodged with me. The debtor states that he first

became aware of insolvency in June, 1918, when the receiver for debenture holders was appointed.

In regard to the failure of Thomas Morrison, the statement of affairs filed by the debtor showed gross liabilities amounting to £2,727 11s. 1d., of which £125 was expected to rank against the estate for dividend. The assets consisted of a bad debt of £199 15s., estimated to be of no value, thus leaving a deficiency of £1,012 17s. 1d.

The Official Receiver's report upon this case is to the following effect:—The receiving order was made on the petition of creditors, the act of bankruptcy being the failure of the debtor to comply with the requirements of a bankruptcy notice before December 15, 1918. The debtor, who is forty-two years of age, states that for about six years prior to May, 1915, he had carried on business as a photographer in Edinburgh. In or about May, 1915, he arranged with a gentleman who had agreed to purchase the machinery and plant of a photographic paper manufactory at Leigh-on-Sea for about £550 to provide the money required to complete the purchase. He sold his business at Edinburgh for £200, and in conjunction with his brother borrowed a further sum of £350. With these sums the purchase was completed, and he and his brother took possession of the business and carried it on under the name of the Leigh Photographic Paper Company.

Eventually, as there was not a quorum of creditors present it was decided to leave the estates in the hands of the Official Receiver, who intimated that if the directors were able to offer a composition to their creditors he would be pleased to consider it.

LEGAL NOTICES.—Notices of intended dividends are given as regards the following failures:—(1) Alfred Ernest Priest, photographer, 21a, Prince of Wales Road, Norwich, and residing at 51, Sprowston Road, Norwich. (2) Harry Saville Thorne, chemist and photographer, 5, Finkle Street, Selby, lately residing at 98, Sackville Street, Barnsley, afterwards at 5, Finkle Street, and 26, Finkle Street, Selby.

DISSOLUTION OF PARTNERSHIP.—Notice is given of the dissolution of partnership between George Bushell and John Kemp Pritchard, carrying on business as photographers at 11, Jewry Street, Winchester, under the style of Rider's Studio. All debts due to and owing by the firm will be received and paid by John Kemp Pritchard, who will continue to carry on the business.

NEW COMPANIES.

DERBY PHOTO WORKS, LTD.—This private company was registered on July 15, with a capital of £2,000, in £1 shares. Objects: To carry on at 92, St. Peter's Street, Derby, the business of photographers and cinematographers and dealers in photographic materials, etc. The subscribers (each with one share) are:—W. H. Hoare, 84, Kedleston Road, Derby, pharmacist; A. Hoare, 84, Kedleston Road, Derby, photographer. The first directors are W. H. Hoare and A. Hoare. Secretary and office: A. Hoare, 92, St. Peter's Street, Derby.

THE JOHNSTON OPTICAL CO., LTD.—This private company was registered on July 16, with a capital of £3,000 in £1 shares. Objects: Opticians, manufacturers of and dealers in photographic instruments and materials, etc. The subscribers (each with one share) are:—Miss A. M. Johnston, Fernbank, Eterby, Carlisle; F. Thompson, Rosslyn House, Carlisle, optician. Directors: H. V. Johnson, J. A. Johnson, Miss A. M. Johnston, F. Thompson, and W. O. Whitehead. Qualification 100 shares. Registered office: 9, Friars Court, Carlisle.

HOME CINEMA CAMERA CO., LTD.—This private company was registered on July 12, with a capital of £2,000, in £1 shares. Objects: To acquire an invention known as the Home Cinema Camera, and to manufacture cameras, cinematographic apparatus, lenses, and photographic appliances. The subscribers (each with 500 shares) are:—A. Barnett, 94, Melrose Avenue, Cricklewood, N.W.2., agent; A. J. Simmons, 19, Cranfield Road, S.E.4, accountant; E. Esdaile, 65, Hene Hill, S.E.24, author. The first directors are A. Barnett, A. J. Simmons, and E. Esdaile. Solicitors: Radcliffe and Co., 32, Walbrook, E.C.4. Registered office: 3, Fulwood Place, Holborn, W.C.1.

VITTY AND SEABORNE, LTD.—This private company was registered on July 14, with a capital of £3,000, in £1 shares. Objects: To adopt agreements (1) between C. P. Vitty and H. G. Seaborne, of the one part, and A. S. Bull, of the other part; and (2) between Bull, Austin, and Co., Ltd., of the one part, and A. S. Bull, of the other part, and to carry on the business of process engravers in line, half-tone, and colour, wood and gravure engravers, printers, photo lithographers, photographers, enlargers, etc. The subscribers (each with one share) are:—C. P. Vitty, The Garth, Brampton Road, St. Albans, process engraver; H. G. Seaborne, Seaton House, Queen's Avenue, Watford, process engraver. The first directors are C. P. Vitty, H. G. Seaborne, and A. S. Bull. The two first-named are permanent managing directors. A. S. Bull is European Traffic Manager to the Sudan Government Railways. Registered office: 3, Crane Court, Fleet Street, E.C.

News and Notes.

PREPAID ADVERTISEMENTS.—Our publishers ask us to give prominence to the intimation that small advertisements are not accepted by telephone for appearance in the "B.J."

BOTTLE SHORTAGE.—In consequence of the scarcity at the present time of wide-mouth bottles of size holding about 1lb., Messrs. Johnsons, of Cross Street, Finsbury, London, E.C., are asking their customers to return empty bottles of this size, and are offering three shillings per dozen for them sent carriage paid. Messrs. Johnsons inform us that the difficulty of obtaining bottles holding about 1lb. of developer is just now a cause of delay in executing orders.

"SEA PIE."—The laughs in the volume of "Sea Pie" now on sale on bookstalls and elsewhere are worth a great deal more than the 1s. 6d. which is charged, and the profits from which go to the King's Fund for Sailors. "Sea Pie" is produced by the officers of the Royal Naval Depot, Crystal Palace, whom every buyer of the book will thank for bringing within its covers a bounty of hearty humour, which is just in the key of the light-hearted holiday maker.

SECONDHAND OPTICAL INSTRUMENTS.—An 80-page catalogue just issued by Messrs. Charles Baker, 244, High Holborn, London, W.C.1., is a unique publication in the specifications it gives of all descriptions of scientific instruments offered second-hand. Microscopes and accessories therefor, are Messrs. Baker's leading line; but photographic and projection apparatus occupy some dozen pages. Messrs. Baker also hold stock of the materials for the Paget and Autochrome colour processes, and are glad to give demonstrations of these methods to those interested at the address given above.

DEATH OF MR. WALTER D. WELFORD.—A once familiar figure in photographic journalism of the past disappears by the death of Mr. Walter D. Welford, sub-editor of "Photography" in the early days of that periodical. Mr. Welford, however, had not been connected with photographic journalism for many years past, although until within a few months of his death he was an active member of the staff of the "Kinematograph Weekly" and was writing cinema plays. In the literature of photography his name survives as that of the author of a manual on the hand camera, in the use of which, in the days before the popular vogue of the hand camera, he was an enthusiast.

VIEW POSTCARDS.—Photographers requiring view postcards from their own negatives and wishing to see the various styles of reproduction available cannot do better than apply to Messrs. Philip G. Hunt and Co., 352, Balham High Road, London, S.W.17, for a portfolio containing specimens of cards in the various styles supplied by Messrs. Hunt. Among real photographs these include the toned glossy, black and sepia, and black and sepia matt. Of photo-mechanical cards there are excellent specimens of collotype, photo-gravure and also of coloured cards in these processes. Messrs. Hunt also supply a photo-mechanical card in imitation of the glossy photograph. The portfolio contains some pages of explanatory notes on the originals for postcard printing and on the times required for executing orders in the various processes.

ROSS SHOWCARDS.—It is impossible for anyone to charge Messrs. Ross, Limited, with neglecting to include the photographic dealer in their peace propaganda of lenses and cameras, for they have just issued a series of close upon a score of different showcards, some very strikingly conceived in colours, others consisting of artistically mounted photographs made with Ross lenses, and still others, exceedingly tasteful cards of about postcard size, such as can be used on a counter or in window dressing. We have been told that the British public will buy British lenses, if only lens makers bring them prominently to their notice. Beyond question, Messrs. Ross have taken most complete measures to collaborate with the dealers to this end. Any dealer who has not received a set of the showcards should apply to Messrs. Ross, Limited, North Side, Clapham, London, S.W.

Correspondence.

. Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

. We do not undertake responsibility for the opinions expressed by our correspondents.

FLATTENING POSTCARDS OR PRINTS.

To the Editors.

Gentlemen,—As I frequently notice that according to the correspondence column of the "B.J." week by week many photographers are in difficulties over the curling of post-cards in drying, and you are constantly being asked for methods of straightening or flattening them, I thought I might be doing a good turn to my brethren in the profession if I described the method I always employ, which is quick, simple, easy and very efficient.

The method by which cards are taken before they are "bone dry" and put under pressure is not satisfactory, because it is uncertain. I have seen a batch of cards in pile taken from pressure by this method as solid as a block of wood, so firmly were they stuck together.

My course of procedure is as follows. After a thorough washing the cards are placed evenly one upon the other upon a sheet of plate glass and a roller squeegee run over them to remove superfluous water. They are then spread out upon sheets of Rohowal blotting paper and left to become quite dry (it is necessary for straightening that they be quite dry).

A clean sheet of brown paper is laid upon the bench upon which the flattening is to be done, the only other utensil required being a small piece of clean card board about 6 ins. by 4 ins. (An old cabinet mount is just the thing).

The post-card is held by the left hand at one end face downwards upon the bench and the piece of card held in the right hand, being firmly pressed down on the back of the postcard. The postcard is then lifted vertically at the same time that the piece of card is drawn with firm pressure from left to right; this part of the process will be found to have flattened the half of the postcard operated upon. The other end of the postcard is then taken in the left hand and the process repeated with the other half. According as to whether the postcard be lifted straight up or bent back over the cardboard in the process so it can be either made flat or to curl slightly in a convex manner.

Care should be taken not to drag the postcard along the bench, thereby perhaps scratching the surface. All that is required is for the post-card to be lifted as the piece of flattening card is applied with sufficient pressure and drawn over the card towards the free end.

This method is thoroughly efficient, no matter how obstinately curled the postcards may have become in drying.

The same process may be employed for prints as well as for post-cards.—Yours faithfully,

M. C. MILDBURN.

43, High Street, Aylesbury.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

J. W.—We have no knowledge of the firm. An English firm supplying certain sizes of ferrotype plates is the Quta Company, 252, Haydons Road, Wimbledon, London, S.W.

A. S.—The Order regarding new retail businesses has not been removed, but if the business of a photographic studio is confined purely to portraits, and does not include the selling of frames of any kind, no licence is required.

F. G.—In a studio the size you give, three 1,000 c.p. lamps should be sufficient. If you apply to the General Electric Company, Ltd., 67, Queen Victoria Street, London, E.C., they will send you full particulars and prices of the half-watts.

J. M.—We do not think you could have more detailed or practical instruction on making up developers, etc., than the article by Mr. Crabtree, which began to appear in the "B.J." of June 27 and was completed in the issue of July 18.

E. S.—The Al Vista camera was sold in this country by Messrs. Houghtons, who could probably furnish you with particulars. The price for the small size, $3\frac{1}{2}$ by 9, was £4 4s.; 4 by 12, £5 5s.; 5 by 12, £6 6s.; and 5 by 16, £10 10s.; but the value now is not great.

N. AND N.—Under the 1911 Copyright Act, which came into force July 1, 1912, registration is now no longer necessary for the purpose of establishing a legal claim to copyright. It is now recognised in law that the production of work such as a photograph creates the copyright in it.

J. H.—You will find an illustration and particulars of a daylight printing box in the "B.J." for March 30, 1917, which our publishers can still supply, price 4½d, post free. It will be difficult to use bromide paper on account of its rapidity, but you could manage well with gaslight paper.

P. A. W.—You can use acetylene light for enlarging (most efficiently with a condenser, although it can be employed for illuminating the negative by reflected light. But a battery of acetylene burners for this purpose is rather awkward to arrange. Write to Messrs. R. J. Moss and Sons, 98, Snow Hill, Birmingham.

E. M.—We do not know of any firm which sells ebonite sheet in small quantities, but think your best plan would be to try one of the electrical supply firms, such as the Economica Electric Co., Twickenham, who supply all kinds of materials for amateur electrical work, and could no doubt obtain for you ebonite sheet if you send them a sample of your requirements.

F. T.—The only preparation made specially for reviving camera bellows is the Bertha reviver, which you can get for a shilling from any photographic dealer. Bookbinders use a book varnish for old corners, which might answer. Your lens appears to be a series IIIa No. 4, the list price of which was £5. It was the least satisfactory of any of the Zeiss anastigmats, and has long since been withdrawn.

M. L.—So far as we know there are no spectacles specially made for retouching. As the eyes are a precious possession you will do well to go to a good oculist's optician and explain your wants to

- him. If you require a very high magnifying power it is a good plan to have the glasses decentred, so that the optic axes may be made to converge a short distance without causing eyestrain. Spectacles so arranged must be used for their special work only.
- T. C.—The prints appear to be terribly over-exposed. Try making a strip test with a slow bromide paper, such as Ilford Slow. At one foot from the candle give, say, 20 seconds, then cover one inch with a card and give another, say, 20 seconds; slip the card further along and give another 40 seconds. Develop for two minutes. If all these are over-exposed, make another test, giving 5, 10, and 20 seconds. This test ought to bring you into the region of correct exposure.
- N. R.—You can obtain a copy of the "Illustrated Guide and Descriptions of Photographic Inter-Lens Shutters" from the author, Mr. William O. Hammer, 1085, 14th Street, San Francisco, Cal., U.S.A. The price is \$2.50 (about 12s. including postage). It is impossible to say what the F /values of the stops are. In the old days every maker marked the apertures as he pleased. If you divide the focal length by the diameters of the openings, it will give you an approximate idea.
- H. T.—Your proposed arrangement of studio should work out quite satisfactorily. As regards the ribbed glass, we do not think this alone will keep out the glare of direct sunlight, so that you will require thin white curtains or blinds in addition, then you will have no trouble. If you want to be able to change over sides when the sun comes on the north-west side you will require the same amount of glazing on the other side, but you only show two narrow windows which do not reach the eaves.
- J. B.—The engine and dynamo will be a comparatively costly affair. If you could buy second-hand we should think £50 is the very least you would need to spend, and probably when you come to buy you will find it is nearer £200. You would have to buy an enormous lot of carbide to compensate for this outlay; in fact, acetylene is a very good light for the Hana printer, or you could get one of the Kitson incandescent lamps from the Kitson Empire Lighting Company, Stamford, Lincolnshire.
- G. M.—It is not possible to say what size of accumulator you will want without knowing the amperage required by your lamp. In any case, we are of opinion that the cost of an accumulator to give a light equal to a good incandescent gaslight such as the "Howellite," sold by Messrs. Griffin, will be out of proportion to the benefit and convenience of an electric light source. We think when you come to make enquiries, say, from a firm of suppliers of accumulators for motor-car lighting, you will find this is the case.
- W. G. A.—1. Addition of bromide tends to give denser not thinner negatives. 2. Potass metabisulphite should be dissolved in cold or at the most tepid water. If dissolved in boiling water part of the preservative sulphurous acid is driven off. 3. Apart from slow paper one cause is fogging of the margins of the bromide paper by light reflected from white paper on the easel or from a light-coloured easel. Try masking the paper with a black mask as soon as it is pinned up on the easel, and see if that improves matters.
- MARKINGS ON LENS.—I have a lens that has been set aside while in the Army. It has the appearance on the surface of prismatic colours as a soap bubble shows. Can anything be done to remove them?—V. R.
- Our advice is to do nothing to the lens, but to keep it in a dry place when not in use to prevent further deterioration. If any attempt is made to remove the tarnish it will probably spoil the definition. If the lens does not appear yellow when looked through, no harm has been done.
- M. G.—1. No licence is needed. If you take photographs "on your own," that is are not paid by somebody else to take them, you have the sole right to reproduce, exhibit, and sell them. 2. We are not quite able to guess what liability you suspect. There is none except the very rare one that the photographs may contain something which is a libel upon some person, but during the past thirty or forty years there have been only one or two cases where it has been possible to restrain publication of photographs on this account. You seem to be imagining some danger which does not exist.

W. G.—The lattice print washer is not intended for standing water, and we do not think would wash evenly unless with running water. There is no better way for you than the dish-to-dish washing. If the prints are fixed in an alum-hypo bath you can eliminate the hypo very quickly by running them through an ordinary laundry wringer between the changes. Six changes of five minutes each would be quite safe, especially with the wringer, which is much used by while-you-wait workers. This method is similar to the sponging, but quicker and more effective; twice through would be enough, once after the first washing water and once after the last.

G. M.—It is rather difficult to advise you with regard to the enlargement. Any stain or dye will tint the high-lights as there is a coating of gelatine on the paper before the carbon image is transferred to it. The only thing we can suggest is to give a thin coating of brown oil paint, using Lyddon's medium, and then to wipe it off the high-lights. To anyone used to the process this would be only the work of half an hour, and when finished the carbon would show no trace of doctoring except the alteration in colour. If the picture is not a large one, we should advise you to have another print done in a warm black. If the negative has not been cleaned off the cost will only be four or five shillings for a 20 by 16.

A. S.—For permission to take photographs, you should apply as follows:—Windsor Castle: Captain Campbell, Holly Lodge, Windsor. Tower of London: Constable of the Tower. Application should be made four or five days ahead, and should be accompanied by some letter of introduction or reference as to identity. Parks: For the Royal Parks—namely, Hyde Park, St. James's, Kensington Gardens, Regents Park, and Bushey Park: the Commissioners of H.M. Works and Public Buildings, Whitehall, London, S.W. Almost all other parks are under the charge of the London County Council, and application should be made to the L.C.C., Spring Gardens, London, S.W. St. Paul's is the worst building in London for getting a good photograph of. Practically the only view point is from an upper window of buildings about half-way down Ludgate Hill. There are plenty of view points for the Tower—namely, on Tower Hill, from the Tower Bridge, and along the Embankment on the Middlesex side, and from one or two places on the Surrey side.

Line Advertisements. Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.
(No reduction for a series.)				

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone or by telegram.

The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed Adv'ts should reach the Publishers on Monday morning.

The insertion of an Advertisement in any definite issue cannot be guaranteed.

ANSWERS TO CORRESPONDENTS	448

SUMMARY.

Consideration of the question of window specimens not the personal work of the photographer raises points which show the difficulty of drawing a hard-and-fast line between what is reprehensible and what is not. The continuance of the exhibition of portraits made by a previous proprietor of a business which has changed hands is commonly considered as unobjectionable, although it may involve as much misrepresentation as the use of bought specimens in starting a new business. In passing judgment upon any case of this kind, it is necessary to examine the individual circumstances. (P. 438.)

In his article this week "Practicus" deals with the intensification of portrait negatives, pointing out how the use of an intensifier may make a negative worse than it was before, and indicating methods of intensification which are particularly serviceable for negatives made in the studio. (P. 439.)

The concluding portion of the paper by M. L. P. Clerc on the correction of aerial negatives taken obliquely deals with the construction of cameras serving to carry out automatically the correction of the distortion introduced by inclination of the lens axis at the time of exposure. (P. 440.)

Although the report of the Eastman Kodak Company for 1918 records a somewhat lower figure for "net earnings," the much larger provision for taxation shows that the company has fully recovered from the set-back in 1917. For 1918 a dividend is declared of 45 per cent. as against 30 per cent. for 1917. (P. 443.)

Co-operative holiday closing of studios, design of enlarging easel, dishes for hypo-alum toning, and suggested tests of plates by the R.P.S. are among the subjects dealt with by correspondents. (P. 446.)

In a County Court case at Hereford a photographer was a successful plaintiff in an action for payment of £37 for a series of commercial photographs. (P. 444.)

Dissatisfaction with the degree of colour correction given by non-screen orthochromatic plates is very often due to insufficient exposure. (P. 438.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

Details are given from the patent specification of Mr. Joseph Shaw of a six-colour method of colour cinematography upon the additive system. (P. 29.)

In a contributed article Lieutenant H. E. Rendall, R.N., in the course of reviewing current methods of making the set of colour-sensitization negatives makes a suggestion for the readier production of such from a line mosaic colour screen plate negative such as the Paget. (P. 31.)

EX CATHEDRA.

No-Screen Ortho Plates. The orthochromatic plate having a dyed emulsion which serves as a screen instead of a separate screen fitted to the lens being required is to-day one of the most popular among all classes of photographers, yet many fail entirely to get the best results from its use. The colour corrective power of such a plate is, of course, limited, and it is not possible to obtain a result upon this type of plate equal to that from a properly screened ortho or panchromatic. The extent of the correction given by the "non-screen" plate is about equal to that of an ordinary ortho used in conjunction with a x2 screen. The bad results (we refer to colour correction) that we have seen with the "non-screen" plate in the hands of inexperienced photographers are almost entirely to be traced to the fact that insufficient exposure has been given. We do not mean that in a technical sense the negatives have been under-exposed, but that *more* exposure is required, in order that the colours of the subject that reflect light of a poor photographic quality may impress themselves fully upon the sensitive emulsion. For the reason mentioned above, many pictures taken upon these plates are no better in the matter of colour rendering than would have been the case with plates of the non-ortho variety. Very full exposures should always be given, where possible, and very much better colour translations will be obtained.

* * *

Towels and Swabs. As a delusion and a snare we do not know of anything which will approach the dark-room towel as usually met with. It is true that it will usually remove a certain amount of moisture from the hands, but at the same time imparts to them a more or less appreciable quantity of such chemicals as may have been used during the previous few weeks. The origin of many mysterious stains and markings upon plates and paper may be traced to this source. As an instance of this, we may relate the case of a photographer who lifted a few negatives out of the fixing bath, and, without rinsing his fingers, wiped them upon the towel. Five minutes later, wishing to make some P.O.P. prints, he carefully washed his hands and dried them upon the *same towel*. When the prints were finished some showed stains in the corners, in spite of his "clean" fingers, and it was not until it was pointed out to him that he realised where the hypo had come from. There is no better plan of securing clean work than that of keeping two or three good swabs by the dark-room sink. These can be used for roughly drying the hands upon, and for mopping up any chemicals which may be spilt upon the benches. A trace of dry amidol floating about may cause endless trouble, but if the bench were swabbed down immediately the mixing of a developer is finished this would be obviated.

The open network swabs, such as are used in bars and restaurants, are the best to use, and they should be frequently rinsed and wrung as dry as possible. Then the towel may be kept to its proper use, that of drying clean hands.

* * *

Speed Numbers. A great many photographers put too much confidence in the speed numbers marked on the labels of their plate boxes without realising that the numbers of one maker are rarely comparable with those on the labels of another. One of the fastest plates that we have ever used was marked with a speed of only 250 H. and D., yet the negatives were equal in every respect, and in some possibly superior, to those taken on plates marked with higher speeds. The fastest plates on the market as a general rule have not the density-giving powers of those of a more moderate speed, and will stand little or no forcing during development. The most important point lies in the photographer having a complete understanding of the behaviour of the most rapid plates that he employs, and particularly of the extent that each may be forced in development without fogging. Every fast plate has some little peculiarity all its own, and it will be found that an understanding of this will be of far more advantage in actual practice than the running after what may be speed numbers of fictitious value.

THE ETHICS OF SPECIMENS.

THE interest which continues to be manifested in the question of photographers showing as specimens work which they have not personally produced shows that the matter is regarded as an important one, and indicates great faith in the value of a good show of pictures as an aid in attracting business; naturally, therefore, the beginner is desirous of acquiring a collection of specimens as soon as, or even before, he has taken down his shutters for the first time.

Undoubtedly the general public regard the prints exhibited by a photographer as genuine specimens of the current work sent out by him, and any departure from this is rightly regarded as more or less fraudulent, whether the specimens have been actually made by him or not, and it may be interesting to consider a few situations having a general bearing upon the question. In the first place there is the case of a man who may have been an amateur or an assistant in another studio who purchases a business and continues it on the strength of the previous proprietor's negatives and reputation, merely changing the name or sometimes trading under the old name to which he is now compelled to add his own as proprietor, although even this need not be done upon the prints, which often are what advertise the studio. Although this is a flagrant case of "bought specimens," we think few of our professional friends would raise any objection to it, because it concerns an established business, and does not bring a new competitor into the field. It is felt rightly enough that if the old standard is maintained things remain as they were, while if the work deteriorates so much the better for the other photographers in the district. It is certain that a man must stand or fall by the work he sells to his sitters, and that though a certain amount of chance trade may be obtained by the window display, it is the current work which secures the steady growth of a business through the recommendation of satisfied patrons.

A somewhat different position is created when an ex-assistant who has legitimately acquired specimens while in employment starts upon his own account. It is well

known to all practical men that it is easier to produce good work in a well lighted studio with perfect apparatus than when handicapped with a more or less unsuitable position and such lenses and cameras as can be cheaply acquired, so that it is quite possible that a lower standard will be attained and the public be disappointed. There are geniuses who can turn out good work under the most adverse conditions, but as was shown in the course of a law case a few years ago, a change from one studio to another even in the same street may play havoc with an established reputation.

The acquirement of a sufficient stock of specimens is quite a stiff problem for the beginner, but if he or she be not prepared to face it in a straightforward way, it would be better to give up the idea of becoming a photographer at all, as it betrays a lack of both skill and confidence in one's own work to shirk it. Every operator has some ideas as to style, and finds it easier to work upon his own lines than to follow other people, therefore he should prepare specimens of a style and quality which he can easily reproduce when sitters begin to come in. There are now three principal ways to become a portrait photographer, the first and most orthodox being to become an assistant or pupil in a good business. This should be the best way, but unfortunately many of the most artistic workers are either averse from teaching their methods or are temperamentally unsuited to do so. Hence there is danger of the novice falling into the hands of those who are out for a big premium, and in return put the pupil to any form of drudgery which may pay him best. As an example of what has actually occurred we may mention a case where a hundred-guinea premium was paid for a two years' term, during nearly the whole of which period the pupil was kept to developing amateurs' films. The prospect of acquiring either specimens or the ability to produce them is in such circumstances a very poor one, and if the victim has the necessary money to start, it is not to be wondered at if he purchases them as he purchases the remainder of his furnishings.

Another door to the profession is from the ranks of the amateurs, which simply means that in many cases people who are desirous of learning photography find that they have to teach themselves, which, with many trials and tribulations, they have succeeded in doing. Such folk are usually quite honest over the specimen question, for they are usually so satisfied with their work that they would not dream of supplementing it by the usual thing.

Yet others follow the American plan of studying photography in a school as others study pharmacy and art. This is an excellent way, as much time is saved by the avoidance of useless experimenting, and after a preliminary period of training in the technique of photography the student can by actual work in the studio acquire confidence in his own powers, and eventually collect a series of portraits and studies which will do him good service when he takes the plunge. There are more photographers in the country who have started in this way than most people imagine.

When we come to enlargements and miniatures we think all requirements are met if customers are supplied with work equal to the samples exhibited, no matter by whom these are made. In most cases the work done by good trade houses which specialise in certain lines is far in advance of anything which the photographer could do on the premises. There is an unfortunate tendency in some quarters to exhibit "first-class finish" work in the window and to supply second-class or even lower grades in fulfilment of orders. This is simply dishonest, and the more so as the price asked would be quite a fair and usual one for the best work.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
 The Camera and the Lens (Jan. 10).
 Managing the Sitter (Jan. 17).
 Backgrounds (Jan. 24).
 Studio Exposures (Jan. 31).
 Artificial Lighting (Feb. 7).
 Printing Processes for Portraiture (Feb. 14).
 Studio Accessories and Furniture (Feb. 21).
 The Surroundings of the Studio (Feb. 28).
 Studio Heating and Ventilation (March 7).
 The Postcard Studio (March 14).
 The Printing-Room (March 21).
 About the Reception Room (March 28).
 Home Portraiture (April 4).
 Portable Studios (April 11).

Copying (April 18).
 Handling the Studio Camera (April 25).
 More About Lenses (May 2).
 Enlargements (May 9).
 Advertising the Studio (May 16).
 Mounts and Mounting (May 23).
 Business Methods (May 30).
 Photographing Children (June 6).
 Portraits of Elderly People (June 13).
 Something about Lenses (June 20).
 Hand Cameras for Professionals (June 27).
 The Dark-Room and Its Fittings (July 4).
 Plates and Their Work (July 11).
 Apparatus Repairs and Renovations (July 18).
 Posing the Head (July 25).

INTENSIFYING PORTRAIT NEGATIVES.

INTENSIFICATION is a process which is now, thanks to a better understanding of the principles of development, not so extensively practised as it was in the earlier days of gelatine plates, when thin images were common, and a large proportion of negatives required strengthening. Still, there are occasions when intensification is absolutely necessary, and others when it is beneficial if done in moderation. In many photographers' minds there is some confusion of ideas as to when intensification is necessary, and negatives which would have yielded a decent print if left alone have been absolutely ruined by the treatment. I will take as an example the portrait of a man in dark clothes, where the exposure has been insufficient and the development prolonged until the face and hands are of fair printing density, but the clothes remain too thin to give any detail in the print. If such a negative be intensified we shall find that the detail in the clothing is certainly improved, but the face and hands have become so dense that the finer gradations are buried, and so much longer printing is necessary that the value of the increased density in the clothing is lost. With such negatives better results may be obtained by treatment with matt varnish or papier mineral, on which the clothing may be strengthened with blacklead, than by a general treatment of the entire image. It is even better to use a soft-printing paper without faking the negative at all than to increase the contrasts, which are already too violent, by intensification. Flat, foggy negatives are also disappointing when intensified in the ordinary way, as the fog is also thickened, so that we get a dense film which is slow to print, and shows little improvement in contrast. If I have such to deal with I usually give them a dip in strong ferricyanide and hypo so as almost to clear the shadows before intensifying, after which the image appears nearly equal to an originally good one.

There are two preliminaries to successful intensification: thorough fixing, and equally thorough washing. If a negative is not properly fixed, we shall find various stains and patches occur during intensification; while if the washing is insufficient, we shall usually find yellow patches, arising from precipitation of the mercury salt used for bleaching. An exception to this is found when mercuric iodide is used, as only a few minutes' washing is needed for this method.

Mercurial intensification is the most popular treatment in most studios, because it is simple, and if properly carried out is fairly permanent. Unfortunately, this is seldom done, as ammonia is commonly used for blackening, and when this

is done it is only a question of months before the negatives turn yellow and lose much of their printing value.

The most general method of using mercuric chloride, or, more popularly, bichloride of mercury, is to make a saturated solution by placing an ounce or more in a twenty-ounce bottle, filling with tepid water, and shaking for a few minutes. A considerable proportion of the crystals will remain undissolved, but this does not matter, as they will dissolve when more water is added to make up the bulk as the solution is used up. The solution may be returned to the bottle after use and allowed to settle. I am always careful only to decant off the clear solution for use, and I am never troubled with pinholes in the negative, which plague some workers. A stronger solution may be made by adding an equal weight of common salt or chloride of ammonium when dissolving the mercury, but I have not found this to be necessary. The negative should be immersed in the mercury solution until it is evenly bleached on both sides, the dish being rocked as in development, or "ripple" marks will appear. After bleaching, the negative must be washed for at least half an hour in running water, or, if this is not available, in frequent changes. I have in the latter case found it useful to put a little common salt in one of the changes, as this increases the solubility of the mercury. After washing, the bleached image must be blackened, and there are several solutions which may be used for this purpose. The most usual and least desirable is a three to five per cent. solution of liquid ammonia. This gives great density, but has a tendency to block up detail in the lights, and is not permanent.

Another and better way is to re-develop in an ordinary amidol or ferrous oxalate developer. Whichever is used, the blackening must be thorough, but in the case of ammonia not allowed to continue after the highest lights have blackened, or a reduction in density will commence, ammonia having a solvent effect upon the image. A few minutes' washing is needed after blackening, and care should be taken that "tear-drops" do not form on the surface, or they will cause irremovable markings when dry.

A better way of employing mercury is to use it in the form of iodide. The solution is a little more trouble to make, but much simpler to use; moreover, any desired degree of density may be obtained, as the action may be stopped at any stage, and the thinner parts strengthened without blocking the high lights. Another useful feature is its applicability to local

intensification, as it may be applied with a brush or pad of cotton-wool where needed. It is made as follows:—

A.—Mercuric chloride 175 grs.
Water 10 ozs.
(Mix this in a 20-oz. bottle.)

B.—Potass. iodide 1 oz.
Water 10 ozs.

Add about two-thirds of B to the 10 ozs. of A, and shake well. There will be a copious red precipitate. Now add more of B, a few drops at a time, until the precipitate is redissolved. The mixed solution may be used repeatedly until it becomes too slow in action. For portrait work it is generally desirable to dilute the solution made as above with an equal bulk of water.

The negative is washed for four or five minutes after fixing, and then immersed in the mercury solution; it becomes rather lighter in colour, but does not quite bleach. When the desired intensity has been attained the negative is washed until the back of the plate shows an orange colour. This is removed by a short immersion in a one per cent. solution of hypo, after which it is thoroughly washed. If the density is too great it may be reduced to any extent by immersion in a plain twenty per cent. hypo bath. Greater density may be attained by substituting an ordinary amidol developer for the hypo bath used to remove the orange colour.

The value of this developer to the portraitist is obvious. Where only one negative of a sitting has to be intensified, it can be done five minutes after fixation is complete, so that the negative can go into the washing tank with the others belonging to the same order. Another good point is that the image, although strengthened, retains its transparency, and keeps a good colour for retouching. The mercury solution keeps well, and when partly exhausted is excellent where only a slight increase of density is required. I may say that in my hands neither the mercuric iodide dissolved in sulphite, as recommended by Lumiere, nor the tabloid form have worked so well as the solution made according to the above formula.

I will now deal with a non-mercurial intensifier which possesses many advantages, not the least being absolute permanence. Its only drawback is that it is a "two-step" method, so that its action cannot be governed in the same way as the

mercuric iodide. The original formulæ of the inventor, Mr. Welborne Piper, will be found in the B.J. Almanac, but as the quantities given are for one ounce only, I give a method of mixing which will be found more convenient in everyday work. Two stock solutions are made, one being potassium bichromate 1 oz., water 10 ozs.; the other, hydrochloric acid (pure, not spirits of salts) 1 oz., water 9 ozs. To make the bleacher for ordinary portrait work, take one part of bichromate solution and three parts of water, and add to each ounce one drachm of the diluted hydrochloric acid. The negative, which needs only slight washing after fixation, is immersed in the solution until bleached (which should occur in about a minute), and is then well washed until the transparent parts are free from the yellow stain. It is re-developed in amidol or metol-hydroquinone until thoroughly blackened. It is desirable to re-develop in diffused daylight, although this is not absolutely necessary with amidol. If the first application does not give sufficient density the whole process may be repeated, but I have never found this necessary with portrait negatives. The colour given is a fine neutral black, and there is no appearance of intensification on the surface. In this it differs from the mercury and ammonia, which leaves a rough surface.

It is very desirable that all intensified negatives, especially those treated with mercury, should be varnished, to prevent their tarnishing by exposure to the atmosphere, and, in the case of platinum printing, action on the paper. If it be inconvenient to varnish, retouching medium may be rubbed all over the surface. This not only serves as a protection, but prevents a mark showing at the edge of the medium, which is almost certain to appear on mercury and ammonia plates.

There are several other intensifiers in ordinary use, but I have not dealt with these, as I have not found them so suitable for our special purpose as those described above. The mercuric bromide and silver cyanide method is an excellent one for very thin and flat negatives, but it is apt to give too much contrast for portrait work, and pure 98 per cent. cyanide is not a desirable chemical for ordinary use. The uranium intensifier has its uses, as it will bring very thin images up to good printing density, but as the image is of an orange colour it is almost impossible to judge of the value of any retouching upon it.

PRACTICUS.

THE PHOTOGRAPHIC CORRECTION OF NEGATIVES TAKEN OBLIQUELY.

[For the purposes of the French Army Aviation Service, in which he was engaged during the greater part of the war, M. L. P. Clerc has investigated with great thoroughness the mathematical conditions involved in transforming a photograph taken from an inclined aerial camera into one corresponding with that obtained from the same view-point, but with the lens-axis vertical. His study has led him to the design of a purely automatic camera carrying out this "redressement." Inasmuch as aerial photographic mapping promises to be an important peace-time application of photography we publish a translation of the text of his paper.—EDS. "B.J."]

(Continued from page 430.)

III. CORRECTION CAMERAS.

§ 15. *General Conditions of Construction.*—Unless one is ready to carry out numerous trial adjustments, which render the correction process really impracticable, it is necessary that the two axes of the rocking frame, themselves parallel, should cut the optical axis at right angles and should be contained in the respective planes of the images, the axes of the frame being thus conjugate to each other as regards the lens which is used—that is to say when the adjustment is made without decentering. In order to allow of a better illumination of the negative to be corrected, when the work is done by artificial light, the axes of the frame should preferably be horizontal, the intersection of the planes then taking place above. The frame should allow of inclinations of, at least, 30 degs.

The negative carrier should hold the negative so that the principal

horizontal of the negative can always be brought to coincide with the axis of the pivoted frame. Use can be made of a plate turntable, allowing of the negative being placed at any desired angle and also of a rise and fall (decentering) movement perpendicular to the axis,⁸ and permitting of bringing the principal horizontal on to the axis even in the case of negatives which have been made in a camera with the lens decentered. In order to assure this coincidence a register line should be made either in the plate-holder or in the negative carrier itself, for example, in the form of a knife-edge capable of being applied on to the image face of the negative and of being withdrawn after adjustment out of the path of the effective light rays. An angular graduation on the plate turn-table of the negative carrier makes it easy to place the negative in its plane.

⁸ There is no object in providing the negative carrier with decentering movement parallel to the axis of the rocker, since a shift of the negative parallel to the direction of its horizontal dimension does not in any way affect the corrected image.

A metric scale, measuring the displacement of the negative when decentered, will facilitate the decentering operation.

The lens should be provided with a shutter operated from outside the camera.

The plate-holder should preferably contain a sheet of glass so as to allow of the use, at choice, of sensitive paper as well as of plates, and even of the tracing of the corrected image on a semi-transparent paper. The front surface of this glass will bear against a rebate in the plane of which is the axis of the frame so as to allow of the glass being replaced without modification of the adjustment.

Graduation of the baseboard of the camera such that the positions of the lens carrier and of either the negative or the plate-holder (the other remaining fixed) for different values of n will serve to restrict the preliminary trials in bringing the two axes of the rocking frame into the positions which correspond to the enlargement desired.

Preferably the camera should include an automatic connection of the lens and the two axes of the swinging frames, so that these latter remain constantly in conjugate positions relatively to each other. A single scale indicating enlargement will then suffice. The negative carrier and the plate-holder may advantageously be provided with graduations giving the value of the angles α and β , or better still the trigonometrical lines of these angles entering into the adjustment formulae. The angles α and β being defined in all cases by their sines (conditions C and D), use will preferably be made of sine indicators*, which can also furnish at the same time the values of the corresponding cosines as an aid to the calculation of decentering.

Preferably the camera should comprise a connection of the planes of the negative and of the corrected image such that the condition (A) is satisfied automatically. If this is done a single sine indicator giving the inclinations β of the plate-holder, or, if the operations are limited to correction without decentering, a sine indicator giving the inclinations α of the negative carrier will suffice.

The size and position of the plate-holder should be such that up to the limit admitted for the angle ω , the corrected image can be entirely formed on the plate or on the sensitive paper. Now, it is easy to be seen (fig. 14)

Fig. 14.

that two equal segments $PA = PB$ on the line of greatest inclination of the negative respectively to the axis of the frame (limits of size in the case of negatives made with a camera with lens central) give unequal images, PA' being greater than PB' . The dissymmetry of the corrected image relatively to the axis of the framework will be appreciably exaggerated if the negative is decentered.

We will now determine the form and the dimensions of the corrected image and the position of the point P' in this image in the case of a 13×18 cm. camera (12×17 effective) of .26 metre focal length, inclined at an angle of $\omega = 30$ degs., the longer side of the plate remaining horizontal, correction being done with a lens of .3 metre focal length without decentering. Here we have
 $m = 1.154$ $n = 2.006$.

The corrected image is identical with that taken from the same view-point on a horizontal plate with a lens of focal length F' , such that

$$F' = n \times \cos 30 \times F = 2.006 \times .866 \times .26 = .45 \text{ metre.}$$

Its enlargement, relatively to the image made from the same view-point on a horizontal plate with a lens of .26 metre focal length is $n \cos \omega = 2.006 \times .866 = 1.732$, and the distance $P'V'$ of the image of the principal point at the vanishing point of the verticals

(image of the point vertically below) is $P'V' = n F \sin \omega = 2.006 \times .26 \times .5 = .26$ metre.

In order to determine the dimensions of the corrected image it will suffice to compare, whilst making allowance for the enlargement calculated above, the dimensions of areas on the ground included on the 12×17 plate from a given altitude, first vertically and then

Fig. 15.

with an inclination of 30 degs. In the vertical view the rectangle included at an altitude of 2,500 metres will measure 1,150 by 1,630 metres: at 30 degs., the trapezium included has bases measuring 1,675 and 2,165 metres, and a height of 1,550 metres, the point immediately below the objective being outside the trapezium and at a distance of 760 metres from its smaller base. We have thus all the elements necessary for the determination (fig. 16) of the form and dimensions of the corrected image.

It will thus be seen that a plate-holder of effective dimensions of 40 by 50 cm., the longer side being placed parallel to the axis

Fig. 16.

of the frame, will permit of registering the whole of the corrected image in the great majority of cases, even when allowing for a slight rotation of the plate in its plane. In order to provide for the decentering of the negative carrier the plate-holder should be fitted with a decentering movement opposite to the intersection of the planes of the negative and of the corrected image.

§ 16. Automatic Connection of Movements of Correction Camera.

—In Fig. 17 is represented a section of the system including negative, lens, and plate-holder on a plane constructed through the optical axis perpendicularly to the planes of the negative and corrected image. At P and P', the intersections of the optical axis with the planes in question, draw perpendiculars to these planes. These straight lines intersect at N. From N let fall a perpendicular on the optical axis, meeting this axis in O'. The angles OMP and O'PN are equal, as are also OMP' and O'P'N. From similar triangles we have

$$\frac{OP}{NO} = \frac{MO}{O'P} \quad \text{and} \quad \frac{OP'}{N'O'} = \frac{M'O'}{O'P'}$$

But $OP' = n OP$ whence $O'P = n O'P'$

and since $OP + O'P = O'P + O'P'$

it follows that

$$O'P' = OP$$

* Consider a jointed parallelogram (Fig. 15), one corner of which is in P on the axis of the rocker, another in Q on the optical axis OP, at the fixed distance PQ from the point P, the side P'Q coinciding with the projection of the plane of the negative, and the corner Q' being free. The straight line PN, perpendicular in P to the plane of the negative, cuts off on Q'Q a segment QR, the length of which, calculated from the right-angled triangle PQR, is

$$QR = PQ \cos \alpha \sin \omega$$

On the other hand, the straight line Q'Q cuts off a segment, $PR = PQ \cos \alpha$.

and that, therefore, the position of O' is independent of the angles α and β , but depends only on the value of n , the locus of N , when α varies, being the perpendicular on the optical axis at O' .

This property has been utilised in the construction of the enlarger-corrector of J. Carpentier (French patent No. 306, 108 of Dec. 8, 1902), a camera in which the axes of the rocking frame are fixed, the

Fig. 17.

enlargement n along the optical axis being constant. It will be seen later that this arrangement can, however, be employed when enlarging and correcting with a variable degree of enlargement.

Another method of connection has been pointed out by G. Labussière. In fig. 18 set off on the optical axis a segment $P'T$ equal to the focal length f of the lens used for correction and draw at T a perpendicular to the axis. At P' draw a perpendicular to the plane

Fig. 18.

$P'B'$ of the corrected image. This latter straight line meets the preceding at U . Join UO , produce this line and let fall upon it from the point P a perpendicular PW . Denoting the angles TOU and $T'P'U$ respectively by α and β , we have

$$TU = P'T \tan \beta = OT \tan \alpha$$

But, with the same symbols as hitherto used, we have

$$OP' = (n + 1) f \text{ whence } OT = OP' - P'T = n f$$

If, now, we replace in the above equation the segments PT and OT by their values we have

$$f \tan \beta = n f \tan \alpha$$

or, after simplification,

$$\tan \beta = n \tan \alpha$$

It is thus seen that the plane PW will be constantly conjugate to $P'B'$ if P is itself the conjugate of P' , their inclinations on a plane at right angles to the optical axis satisfying condition (A).

For the establishment of a mechanical connection based on this property, we can join together two jointed parallelograms ABA_1B_1 , A_2B_2 , one of the sides AB coinciding with the intersection of the plane of the negative, whilst the opposite side A_2B_2 has a point fixed at O and is connected to the straight line OU perpendicular at O to A_2B_2 . The arms AA_1 and AA_2 will be chosen of length such that OP can be of any length, corresponding to the required degree of enlargement. A guide groove TU , engaged by the rear element of the camera at the fixed distance f from the axis of the pivoted frame will keep the intersection of the arms $P'U$ and OU in the necessary position.

Mention may be made, by way of review, of two methods of connection described in the patent of Th. Scheimpflug (French patent No. 339,655 of Jan. 16, 1904), which sets forth, though in a somewhat confused way, the principles employed in the construction of a series of correction cameras. The different elements of the camera are mounted on concentric racks having their centre at M (fig. 19).

Fig. 19.

Each of the parts, negative carrier, lens, and plate-holder, is in a radial plane of the cylinder, the axis of which is perpendicular at M to the plane of the racks, and can slide in its plane so as to be capable of being brought to any required distance from the axis M . The other construction is applicable only to the case where the two axes of the frame are conjugate to each other and equidistant

Fig. 20.

from the optical centre, say each at the distance of $2f$ from the latter. Angling of the planes of the negative and of the image is transmitted by a system of three angular pinions (fig. 20) having arms turning round the same axes as the planes in question. The arms turn through angles equal but opposite to those through which the planes turn. In order to assure the adjustment it is sufficient

Fig. 21.

that the intersection m of these two arms shall be kept in the straight line OM perpendicular at O to the optical axis.

Of other approximate methods of connection, suitable only for very small angles, and, therefore, of little use for cartographic work, may be mentioned those of Pasqueau, J. Olive, and R. Aubry.

§17. *Automatic Enlarger-Corrector of L. P. Clerc.*—In October, 1916, the present writer pointed out the possibility of constructing an automatic correcting camera permitting of variable enlargement, and had a demonstration model of it made.

The conjugation of the axes of the swinging frame relatively to the lens is obtained by an "inverter" of Paucel'ier previously described by G. Koenigs (French patent No. 300,117 of May 9, 1900) for the construction of ordinary photographic enlargers. In fig. 21 is shown the diamond quadrilateral A B C B', each side of which measures *a*. Take a point O on the axis AC and join this point to the two apices B and B' by arms of length O B = O B' = *b*. Construct the other diagonal of the figure and let D be its intersection with A C. Calling the distances O A and O C respectively *x* and *y*, from the symmetry of the figure with regard to B B', we have

$$O D = \frac{x - y}{2} \quad A D = \frac{x + y}{2}$$

From the rectangular triangles A B D and O B D we have
 $B D^2 = A B^2 - A D^2 = B O^2 - O D^2$
 which can be written

$$A^2 - \left(\frac{x + y}{2}\right)^2 = b^2 - \left(\frac{x - y}{2}\right)^2 \text{ or } x y = a^2 b^2$$

If the diamond quadrilateral is jointed so that the points A, O, and C lie constantly in the same straight line, the above relation will be maintained whatever may be the respective positions of these points. Now, the law of conjugate points may be written

$$(p - f)(p' - f) = f^2$$

If the lengths of *a* and *b* are chosen so that $a^2 - b^2 = f^2$, and if on the axis A C we bring each time opposite to the point O the segments A P = C P' = *f*, the points P and P' will be constantly in the conjugate positions for a lens of focal length *f* having its optical centre at O.

In order to combine this form of connection with the first of those for the connection of the swinging frames described in a preceding paragraph, it suffices to control the displacement on A C of a point O' such that A O = C O', and, therefore, also O P = O' P', which can readily be done by the two arms B O' and B' O' of length *b*. Fig. 22 shows the arrangement adopted for the construction of the test model, supplementary connecting rods serving to ensure the parallelism of the lens carrier and of the frame in

Fig. 22.

which are fitted the guide grooves for the connection of the swinging frames. The negative carrier is provided with a sine indicator.

This form of connection is not adapted for same-size reproduction, nor for a moderate degree of enlargement for which *n* has nearly the value of 1. But we saw that, in the case of correction without decentering, the correcting lens could be chosen with advantage so that the enlargement would always be in the neighbourhood of *n* = 2. In order even to permit of reduction being made with this camera, for example, in bringing corrected photographs to scale, the negative carrier and the plate-holder should be made interchangeable. In the case where it would be necessary to make a reduction or enlargement on a scale for which *n* is nearly equal to 1 we should proceed successively to make an enlargement of *n*₁ and a reduction of *n*₂ such that *n*₁*n*₂ = *n*, *n*₁ and *n*₂ may be chosen so as to come within the limits permitted by the camera. The

complication is more apparent than real. If we start with the original negative, the corrected image is a positive, and it is necessary to make a negative for reduction to scale. In the case where a double operation would be necessary the final prints would be made not by contact, but by enlargement.

In the case where we would require to correct negatives made with a camera the lens of which had a focal length not in satisfactory

Fig. 23.

accordance with the focal length of the correcting lens, we should first make a preliminary reduction of the original negative, thus bringing its equivalent focal length to the required value.

In one special construction the transverse bulk of the connecting system could be reduced by adopting a series of jointed parallelograms, for example, coupling two series of three parallelograms (fig. 23) together. All the transverse dimensions would then be reduced two-thirds, and the lengths *a'* and *b'* of the arms would then be such that

$$a'^2 - b'^2 = \frac{f^2}{9}$$

L. P. CLERC.

[Correction.—The last sentence in the last instalment of M. Clerc's paper, namely, on p. 430 of our issue of July 25, should read as follows: "Denoting, as already done, the equivalent focal length of the corrected photograph by F' and the focal length of the correction camera lens by F/m, we have"—Eds. B.J.]

EASTMAN KODAK COMPANY.

THE annual report of the directors of the Eastman Kodak Company for the year ending December 31, 1918, shows that the Company and its subsidiary undertakings are further progressing in their recovery from the set back in profit-making which was disclosed by the previous report, namely, that for the year ending December 31, 1917. In this latter year, as is shown by the statement of annual earnings since the year 1900, the net profits of the Company fell from, in round numbers, three and a-half million pounds to three million pounds. The figure for the net earnings for last year, namely, £2,897,313, certainly shows a further small decline from the total of 1917, but it must not be overlooked that the practice of showing as net earnings the amount which remains after taxation has been deducted, is one which masks the real profits of a company in comparison with previous years if taxation varies greatly as it has done during the last few years. Thus in the 1917 report the provision for war excess profits and income-taxes was only £824,000 as compared with £1,492,000 for 1918. We add the figure for 1918 to the statement given below, although, as we have just said, its smaller amount really represents greater incidence of taxation to an extent which has considerably counterbalanced the improvements in the Company's business.

Year ending December 31,	£
1900	465,816
1901	517,347
1902	564,455
1903	606,740
1904	688,484
1905	827,610
1906	1,116,639
1907	1,446,479
1908	1,540,725
1909	1,619,087
1910	1,850,552
1911	2,401,910
1912	2,886,401
1913	2,920,090
1914	2,332,579
1915	3,245,600
1916	3,564,784
1917	2,998,467
1918	2,897,313

For the year ending 1918, dividend payments amounting to 45 per

cent. were paid upon the common stock as against 30 per cent. for 1917. A further item in the 1918 balance-sheet which attracts attention is the increased figure at which "merchandise, materials, and supplies on hand" stand, namely, £4,757,000 as against £3,664,000 for 1917. It is evident that the Company has very speedily recovered from the set-back which it received in 1917. Its increase of dividend distribution corresponds with this recovery, whilst the marking up of the common stock on the Stock Exchange to a figure of its pre-war level, and higher, shows that investors take a confident view of the immediate capacity of the company for increased earnings.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications:—July 14 to July 18.

CATALOGUES AND TRADE NOTICES.

MR. B. V. SEXTON, trade and commercial photographer, of Bellevue Road, Southampton, sends us his 8-page list of prices for enlarging and printing, a copy of which may be had on application.

A WELLINGTON BOOKLET of a most attractive kind has just been issued by Messrs. Wellington and Ward, chiefly by way of emphasising the value of the Wellington Anti-Screen plates to the holiday-maker. Incidentally the booklet is a pictorial story of the charm of photography by sea, lake, or mountain. Messrs. Wellington and Ward will be glad to send a copy to any applicant.

ILFORD BROMIDE PAPERS.—Messrs. Ilford, Limited, have just issued a revised edition of the little instruction manual on the use of their bromide and gaslight papers. The manual deals in a thoroughly practical way with the clearing, toning, and glazing of prints and enlargements, and as a supplement to it the Ilford Company are prepared to send to bona-fide professional photographers a portfolio of six prints showing the results produced on the various grades of Ilford bromide. The prints, which are fine examples of portrait photography, admirably serve to show the very high technical excellence of the Ilford papers.

Commercial & Legal Intelligence.

A CLAIM FOR COMMERCIAL PHOTOGRAPHS.—An adjourned action, Croot Tucker v. Kerr, was tried at Hereford County Court last week, before His Honour Deputy Judge Hargreaves. The subject of dispute was a series of photographs of the extensions at the Hereford Corporation Electricity Works made during the war. The plaintiff was Mr. John Samuel Croot Tucker, 22, Commercial Street, Hereford, and the defendant was Mr. Wm. Talbot Kerr, electrical engineer to the Hereford City Council. A total of £37 16s. was claimed, the items being as follow: Making twenty 12in. by 10in. negatives and submitting twenty rough proofs; eighteen prints at 25s. each, set in portfolio, and 102 unmounted prints at 3s. each.

Mr. S. R. C. Bosanquet was counsel for the plaintiff, and Mr. A. B. Whitfield for the defendant.

Mr. Bosanquet, in outlining the plaintiff's case, said Mr. Kerr requested Mr. Tucker to take some photographs for him of the new electrical installation at Hereford. The precise object for which they were wanted was not material to the plaintiff, and as a matter of fact he was not informed what it was. Plaintiff agreed to do the work, but no special terms were arranged. They were to be large-sized photographs, and the plaintiff exposed a number of plates. Mr. Tucker had to go down to the works on many occasions and spent a very long time there, the taking of the pictures necessitating also a very high degree of skill. The negatives were obtained under great difficulties owing to the cramped positions, absence of light, and trouble from reflections. The order was executed to Mr. Kerr's instructions, but when the bill was sent in defendant suggested that the prints were taken for the Hereford Corporation, and endeavoured to refer Mr. Tucker to that body for payment. Then subsequently plaintiff was told that the pictures were for the Electrical Brush Company, and then again they were for the Ministry of Munitions. Coming to the value of the work, Counsel mentioned that the three dozen 12in. by 10in. plates alone cost £4 5s. 6d.

Mr. Whitfield here interposed to explain that the defendant would not dispute the amount of the claim if his Honour found that the contract had been fulfilled. The defence was, firstly, that the photographs were not done in time for the purpose for which Mr. Kerr required them, and, secondly, that they were of no value for the purpose for which they were required.

The plaintiff said defendant called on him at the shop about taking the photographs, and witness asked what they were wanted for. Mr. Kerr told him to go down to the works and see Mr. Watson, and he would show him what was required. Mr. Watson, who was second in charge of the works, showed him round the whole of the plant, pointed out the objects to be photographed and the positions from which they should be taken. The work required a good deal of time and skill. For the purpose of taking one particular view he had to purchase a special short-focus lens. To get some of the pictures special platforms had to be provided, and these were put up by Mr. Kerr's own men. He submitted the pictures to Mr. Kerr in rough proof form, so that defendant could say what should be blocked out and what left in. Witness followed Mr. Kerr's instructions on these points, and when the finished prints were submitted he asked Mr. Kerr whether they were satisfactory. Mr. Kerr replied, "Yes, quite." It was never till now suggested that the photographs were no use, and he heard nothing derogatory about them until the beginning of this year.

Reginald Herbert Scott, of Birmingham, a photographer with twenty-five years' experience, gave evidence in support of the claim. Many of the photographs, he said, were exceptionally good, and as a whole they were all good commercial photographs for the purpose for which they were taken. In cross-examination, however, he admitted that he had not seen the machinery the subject of the pictures.

This concluded the plaintiff's case.

The defendant, in the witness-box, stated that in 1916 the Hereford Corporation, to which he was electrical engineer, arranged with the Ministry of Munitions to make extensions to the electrical works to supply current to No. 14 National Filling Factory. Owing to the exigencies of the war there was no time for plans to be prepared

in the ordinary way, and he decided to have photographs taken to illustrate the work done to put before the Ministry. He engaged Mr. Tucker to supply the photographs, and told him he wanted the machinery taken in clear detail to send to the Ministry; the photographs had also to be deposited with the Local Government Board. He asked Mr. Croot Tucker if he had ever done any photographs for reproduction in technical journals, and he said "Yes." Witness said, "Then you understand what we want." Witness stipulated that the order was to be executed by June 17, as by that date he had to submit a report to the Ministry justifying the expenditure. The expenditure at the works amounted to £96,000, involving twenty-nine different contracts, and he had to account to the Ministry for every detail. He recognised when ordering the photographs that there were difficulties from the photographic point of view, but the staff afforded plaintiff every facility in regard to erecting platforms and in other ways. Mr. Tucker undertook the work, but did not deliver the photographs in time to be incorporated in his report to the Ministry; they therefore were useless to him. But as they had been taken he thought perhaps the firms having contracts on the works would like photographs of their different pieces of machinery and that these might do. So he wrote and asked them in Mr. Tucker's interests. Apart from late delivery, the photographs were useless for the purpose for which he wanted them, as they did not show the machinery in sufficient detail, and it would have been a "discreditable production" for him to incorporate in his report.

Wm. Geo. Osborne, electrical engineer for the Brush Electrical Engineering Company, Loughborough, one of the contracting firms in the Hereford electrical extensions, gave evidence for the defence, saying that plaintiff's photographs of his firm's machinery were of no use to engineers, as they did not show important details and the relative positions of vital sections. Photographs like those shown him by Counsel (taken by another photographer) for comparison would, he said, be useful to an engineer.

Mr. Whitfield submitted that in this case there was an implied warranty under the Sale of Goods Act which had not been complied with, because the photographs were not reasonably fit for the purpose for which they were required.

Mr. Bosanquet replied that the photographs were accepted by the defendant, were not sent back, and nothing was said about them not being fit for the purpose for which they were required until long after the bill was sent in.

The Judge, in giving a decision in favour of plaintiff, said he could not accept defendant's contention that the photographs were too late; he never wrote a letter which he could produce complaining that they were not in time. He accepted his statement that he would have liked to use them on June 17, but he could not hold that that formed part of the contract. The other defence to the action had caused him more difficulty, because of conflicting expert opinions. On this point, however, he had come to the conclusion that they were fit for the purpose for which they were required so far as those requirements were expressed at the time the contract was entered into. Defendant was accepting delivery of the prints over a long period without objecting to them, and he could not now expect the Court to take the view that they were useless for his purpose.

Judgment was entered for plaintiff for the amount claimed with costs.

LEGAL NOTICES.—Notice is given of the dissolution of the partnership between William James Davis and Louis Arbus, carrying on business as photographers at 10, Preston Street, Brighton, under the style of Arbus and Davis. All debts due to and owing by the late firm will be received and paid by W. J. Davis, who will carry on the business.

Notice of intended dividend is given in the failure of Charles Frederick Siedle (trading under the style of Siedle Bros.), photographer, 60, Walter Road, Swansea, and 13, Heathfield Street, Swansea. August 2 is the last day for lodging proofs with the Official Receiver (Mr. Henry Rees), Government Buildings, St. Mary's Street, Swansea.

Notice of intended dividend is given in the failure of Joseph Edmund Bramwell, photographer, lately carrying on business at 124, Westborough, Scarborough. Proofs must be lodged on or before August 9 with Mr. D. S. Mackay, Official Receiver, 48, Westborough, Scarborough.

NEW COMPANIES.

MAWSON CO., LTD.—This private company was registered on July 17, with a capital of £20,000 in £1 shares (10,000 pref.). Objects: To carry on the business of manufacturers and dealers in all kinds of photographic dry plates, films, and papers, photographic chemicals, collodions, collodion emulsions and varnishes, photographic apparatus, surgical, optical, and dental instruments, etc., and to adopt an agreement with D. Blount and W. H. Bacon. The subscribers (each with one share) are:—D. Blount, 59, Brighton Grove, Newcastle-on-Tyne, photographer; A. Payne, 49, North Parade, Whitley Bay, chemist. The first directors are D. Blount and W. H. Bacon, 7, Eslington Terrace, Newcastle-on-Tyne (both permanent), and A. Payne. Qualification, 100 ordinary shares. Registered office, 81, Northumberland Street, Newcastle-on-Tyne.

LONDON ETCHING CO. (1919), LTD.—This private company was registered on July 21, with a capital of £3,000 in £1 shares (1,500 pref.). Objects: To adopt an agreement between the London Etching Co., Ltd. (in liquidation), and this company, and to carry on the business of colour process and half-tone and line engravers, photo etchers, stationers, printers, lithographers, stereotypers, electrotypers, photographic printers, etc. The subscribers (each with one share) are:—G. W. W. Wright-Nooth, 16, Cranbourne Gardens, Temple Fortune, Golders Green, N.W.4, artist; W. L. McNay, 2, Scarsdale Terrace, Kensington High Street, W., photo engraver. Directors:—G. W. W. Wright-Nooth and W. L. McNay (permanent joint managers). Qualification, £100. Registered office, 3, Holborn Place, High Holborn.

AERIAL PHOTOS, LTD.—This private company was registered in Edinburgh on July 18, with a capital of £18,000 in £1 shares. Objects: To carry on the business of (a) aerial photography, including cinematograph films; (b) aerial passenger transit; and (c) commercial aerial advertising, etc. Agreement with Captain R. S. J. B. Andrews, Major C. H. C. Smith, and Captain O. Hardie. The subscribers (each with one share) are:—H. E. Haig, Clayton, Dairsie, Fife, paper maker; A. R. Wilson Wood, 7, Abbotsford Crescent, St. Andrews, Fife, gentleman; L. W. Allen, 77, Station Street, Coventry. The first directors are Captain R. S. J. B. Andrews, C. H. C. Smith, and O. Hardie. Registered office, 81a, George Street, Edinburgh.

News and Notes.

DONCASTER CAMERA CLUB.—All communications should be addressed to Mr. J. Tremayne Blackshaw, 33, Hall Gate, Doncaster.

MR. J. RUBIN, 241, Old Kent Road, S.E., writing in reference to the report on page 383 of our issue of July 4 last, of an alleged fire, asks us to make a correction. He informs us that the slight damage done to the premises was by smoke from an outside source, there having been no fire within the building.

"THE PROFESSIONAL PHOTOGRAPHER" for July contains illustrated interviews with Mr. J. R. Browning, of Exeter, and Mr. Leon Leyson, of Johannesburg. An article by Mr. F. C. Tilney offers some suggestions on the eternal question of expression in portraiture, whilst the advertisement pages of our Kodak contemporary are devoted chiefly to new introductions in folder mounts.

STOLEN SANDERSON CAMERA.—Messrs. Houghtons, Limited, notify us that a half-plate Tropical Sanderson camera, No. 24877, fitted with a Ross Homocentric lens, Nos. 83794 and 16357, in Koilos shutter, was stolen in Commercial Road, London, E., from a van belonging to Messrs. Ford, the carriers. Messrs. Houghtons will be grateful if any dealer to whom the outfit may be offered will communicate with them.

STOLEN BUTCHER CAMERAS.—Messrs. W. Butcher and Sons, Limited, Camera House, Farringdon Avenue, London, E.C.4, advise us that two watch pocket Carbine cameras, Nos. 69,409 and 64,920, were stolen from their premises last week. The cameras are fitted with Aldis Uno lenses in Lukos H. shutters. Notification of the theft has been made, and any dealer having the cameras offered to him for sale will oblige Messrs. Butcher by communicating with the police.

A "BEAUTIFUL RICHMOND" COMPETITION.—The Richmond Camera Club are organising a competition in which money prizes from five guineas to half a guinea are offered for the best set of six prints illustrating the beauties of Richmond, Surrey. The set must not include more than one print of a subject in Kew Gardens. The competition is open, without entrance fee, to any photographer, either professional or amateur. Entry form and further particulars may be obtained from the treasurer of the Richmond Camera Club, 61, George Street, Richmond. The latest date for the receipt of prints is October 11.

MESSRS. JOHNSON AND SONS, of 23, Cross Street, London, E.C.2, advise us that they still have a few vacant dates for the illustrated lecture by their representative on "Photography in the War," for the 1919-20 session. The lecture deals with photography in its application to air, naval, and field warfare, hospital work, recreation, etc., and is illustrated by over 100 slides. Messrs. Johnson are also prepared to give either of their other demonstrations, "The Art of Developing" and "Printing Processes," before photographic societies. Any secretary who wishes to book any of the above-mentioned three fixtures is asked to make application without delay.

THE "TIMES," which, as is known, has interested itself for several years past in the use of rotary photogravure for newspaper illustration, has now begun to issue, as a supplement to its weekly edition, an 8-page sheet of photogravure reproductions of topical photographs. The issue in which this feature started was that of July 25, and the illustrations appropriately give prominence to the peace celebrations in London of July 19. The technical quality of the rotogravure supplement is of a very high order, and the new feature will undoubtedly do much further to recommend the weekly edition of the "Times" to its many readers throughout the world, who for many years past have found its text pages the most valuable means of following the course of events in England and the European continent.

MR. WILLIAM MARSHALL, of Henley-on-Thames, has, through Messrs. Abbott, Booty and Company, disposed of his old-established business carried on there to Mr. George Bushell, late partner of Bushell and Pritchard, of Winchester. The business is one of a specially interesting kind, from the fact of Mr. Marshall having installed his own electric lighting plant and thus offering the facilities of electric light portraiture in a town without any electric public service. Mr. Marshall had also introduced many ingenious labour-saving devices for printing and enlarging, of which a description appeared in the "B.J." of March 30, 1917. The little town of Henley can hardly be called a focus of business except for the month or two of the river season, but Mr. Marshall's enterprise supplies a useful object-lesson to photographers of what can be done by the energetic adoption of modern facilities.

Correspondence.

. Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

. We do not undertake responsibility for the opinions expressed by our correspondents.

A PROFESSIONAL PHOTOGRAPHIC ASSISTANTS' ASSOCIATION.

To the Editors.

Gentlemen,—I would like to emphasise the concluding remarks in Mr. Aspden's letter in your issue of the 18th ult., but at the same time fail to see how such an association will benefit by the patronage of the master photographers' associations.

The very name of the latter society savours of arrogance, and in my experience of being employed for the last eight years by a very prominent member of that association goes for anything, then the less assistants have to do with that body the better it will be for them.

Whilst it is very desirable, in these latter days, for assistants to

have a union, and personally I hope such an association will be formed, I await with lively anticipation the first crossing of swords with the august "Master Photographers' Association."—Yours faithfully,

EXPERIENCE.

CO-OPERATIVE HOLIDAY CLOSING OF STUDIOS.

To the Editors.

Gentlemen,—It may interest your readers to know that most of the Northampton and district photographers have agreed to close their studios during the ensuing Bank Holiday week. It will be remembered that the Northampton photographers were the pioneers in this movement, and that in the two previous years of combined closing the arrangement has been mutually satisfactory to both employers and assistants. Things have not worked quite so smoothly this year owing to the aloofness of one of the leading craftsmen and a prominent member of the P.P.A., who, for reasons best known to himself, has given us no clue of his intentions. However, almost all of us are acting quite independently of whether he opens or not, and hope the public will take due notice. The response of the district photographers in such places as Kettering, Wellingborough, Rushden, and Wolverton is very encouraging, and the bulk have decided to close until the Friday, and some all the week.

If photographers can combine on this matter, why not on others quite as important affecting the status and progress of the profession? Are the P.P.A. Council alive to their responsibilities of sagacious leadership?—Faithfully yours,

S. H. GREENWAY.

27a, Abington Street, Northampton.

STEREOSCOPIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—As many readers may have had their interests in this subject revived by the articles of C. E. B. which you have recently given us, I send you a drawing of the simplest form of stereoscope probably ever made. I bought it several years ago for a few pence. It was patented, I think, but the patent has probably

Fig. 1.

Fig. 2.

run out long ago. It consists of a small piece of plate-glass, shown in plan in Fig. 1. The central division is blackened, and the ends are bevelled (and polished). The flat side is held towards the picture at a distance of about 3 inches from the eyes. Fig. 2 is a section.

Epsom, July 18, 1919.

TRAVERS J. BRIANT.

A HOLDER FOR BROMIDE PAPER ON THE ENLARGING EASEL.

To the Editors.

Gentlemen,—Some time ago one of your subscribers gave us, through your columns, a device for holding the bromide paper when enlarging. Doubtless you will remember the idea; it was some umbrella ribs at each corner of the enlarging screen made to draw in and out. I tried this, but the ends projected, and were somewhat in the way, so I enclose another very simple idea which I have adapted as it answers well for all sizes. After deciding what size you wish your largest enlargement to be, you make a hole right through at each corner of your screen carrying the bromide paper, as per sketch. Then push through a strong elastic band on the back of the screen, place a piece of wood through the elastic band projecting out of the hole, and on the other side insert the rod to hold the

brass bar which holds the paper in position just where you want it by raising it up or down according to the size. The same is done both sides of the screen. Four elastic bands will be required, one

for each hole. The enclosed sketch will, I think, explain itself. BB are the crossbars, and AAAA elastic bands passed through the holes in the easel.—Yours faithfully,

G. H. EUSTACE.

306, Cleethorpe Road, Grimsby.

METAL DISHES FOR THE HYPO-ALUM TONING BATH.

To the Editors.

Gentlemen,—With reference to your opinion expressed in the "British Journal," May 22, 1919, page 287, that "no metal dish is immune from liability to give spots in hypo-alum toning," and that "we should view a lead-coated dish with suspicion," we have made a number of experiments to determine whether it is possible to use metallic lead in contact with a hypo-alum toning bath, and find that a bath which has been left in intimate contact with pure lead for one week is almost useless, being far slower in action than the normal bath, and also giving stains particularly on the backs of the prints. From our experiments it is apparent that the presence of metallic lead causes additional reactions which can possibly be represented by the following equations:—

There is little doubt that the metallic lead is continually converted into lead sulphide, while the dissolved silver salt (present normally in a hypo-alum bath) is changed to metallic silver or silver sulphide.

In general it would appear that any metal which combines at all readily with "nascent" (in this case a microscopic and incipiently colloidal) sulphur or which displaces silver from its thio-sulphate-complex solution, is not suitable as a container for hypo-alum toning baths.—Very truly yours,

E. R. BULLOCK.

J. I. CRABTREE.

Research Laboratory, Eastman Kodak Co.

Rochester, July 10.

[We have it on the authority of one of the largest makers of toned prints that a dish of pure tin is quite satisfactory for the hypo-alum toning bath.—Eds. "B.J."]

PLATE TESTS—A SUGGESTION TO THE R.P.S.

To the Editors.

Gentlemen,—The R.P.S., in its endeavours to be a greater power among photographers, might take a hint from the R.A.C., who before the war conducted stringent tests of motor cars and accessories, finally issuing certificates. The conditions under which these trials were carried out were such that a good certificate was of great advertising value. In addition, the fairness was such that no firm would have a chance in a libel action. My suggestion is that the R.P.S. should do something of the same sort for photographers, making a start with plates and papers. Perhaps later it might be found possible to devise some camera tests. Plates

could be tested for gradation, latitude, and keeping quality. For the first we might have an actinometer with about 40 graduated tints from plain glass to complete opacity. A plate capable of rendering 25 tints, for example, would have its gradation registered as 25, and so it would be very easy to compare plates by this simple system.

The last test is what interests me most of all, and to show why I will give a short extract from my photographic life. In 1915, gulled by the advertisements of a plate firm, I bought 12 dozen plates to take to Madeira. Alas! they soon faded away under the sub-tropic heat, while a friend with a different brand went on merrily snapshotting. The scene now changes to the winter of 1918, when I arrived in North Russia, armed with three makes of plates—self-screen, Wratten, and Paget panchromatic. I met there a gay young amateur, who had come out a month before. Yes! he was going to show me how to take photographs; at once challenged me to produce a better negative, etc. Naturally I was interested to know what make of plates such a redoubtable opponent was using. Oh, the best in the world—XYZ plates. These XYZ plates were that brand that had let me down in Madeira. Now the fun's going to begin, I thought. It was not long before he borrowed my darkroom and developed his Murmansk exposures. Horrid, thin, smoky negatives, with a deep stain round the edges. We put this down to the sea voyage and absence of the sun. However, things got worse. When circumstances combined to produce a reasonable negative it was always disfigured by pinholes and a dirty appearance. We made careful comparative trials, exposing and developing two makes at the same time, and the inferiority of XYZ plates was very marked. The three brands of plate I have chosen are going on giving good results, in spite of the great variation of temperature that they have been through—i.e., from Arctic cold to the short, fierce summer, which is almost sub-tropical in its intensity. I forgot to mention a speed test; also we should expect a few remarks on the tendency to frill, pinholes, etc.

The technical part of the tests could be worked out and performed without looking for a reincarnation of Hurter and Driffield. I can imagine a neat row of incubators for plates undergoing the "keeping" test; and what more interesting than to see the condition of the operator as he comes out of the special tropical darkroom? One of the conditions for test would be that the plates must be bought by a private buyer, appointed by the society. Once the plates are bought the trial would have to be carried out and published, so that if the buyer happened to get hold of a stale plate vendor there might be some sporting by-play between the makers and vendors, all toning up the trade for the benefit of the user. Gaslight paper tests on these lines would probably provide a lot of fun.

Cameras would be tested for the following:—

- (1) Parallelism of lens with plate.
- (2) Registration of ground-glass with sensitive surface, any inaccuracy being measured and noted on the certificate.
- (3) Accuracy of focussing scale.

I have no doubt that some such trials would add enormously to the prestige of the society.

H. E. RENDALL.

H.M.S. M25, c/o G.P.O., London.

July 6.

THE IMPERIAL HANDBOOK, 1919.—The little annual miscellany of notes and articles which year by year makes its own welcome among the pieces of technical reading for the amateur photographer, is just issued by the Imperial Dry Plate Company, with the warlike Imperial lion relegated to a minor position on the back cover and the front occupied by a design symbolical of the new age of peace and justice. An immense golden sun is, we hope, rising, although it is difficult to determine the artist's intention of its position in reference to the Nelson statue which towers above it. The beginner in photography, and many of the experienced, for the matter of that, will accord a profitable reading to the notes on child portraiture, the pyro-soda developer, the making of enlargements, and other subjects which occupy the pages of the Imperial annual. A copy may be had on application to the Imperial Dry Plate Company, Cricklewood, London, N.W.3.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

J. E. C.—We think Mr. R. E. Peeling, 4-6, Holborn Circus, E.C., would be able to make an effective repair of your shutter.

C. C.—All postal censorship has now been removed, so that you are at liberty to send any photographs to neutral countries, and, we believe, also to previously enemy countries.

N. E.—Ferro-prussiate or white-line paper can be quite easily made (see formula in the "Almanac"), but the other papers, such as ferro-gallic, are not within the scope of home preparation, and even if you want to make ferro-prussiate in large quantity you will have to put down a coating machine since hand application of the sensitiser would be a very laborious job.

J. G.—Almost certainly the mischief will be done by the time the enlargements have been mounted. This is bound to be the case if the cause of the fading is incomplete fixing, and in all probability will also be the case if the fading is due to impure mountant or mounting board. These are two most common causes of fading. There is really no benefit in refixing after enlargements have once been mounted.

G. M.—The photograph is probably either a collodion positive or a Daguerreotype. In either case it is very delicate and most easily damaged. It may be possible to restore it, but the best thing you can do is to send it to a professional restorer, such as Mr. Charles Debenham, 222, West End Lane, Hampstead, N.W. If it is not capable of restoration then your best course would be to have it sent to an expert copyist such as Mr. Stewart Bale, 53, Lord Street, Liverpool.

H. E.—Perhaps the best thing we can do is to send you a copy of the schedule of prices issued last month in a revised form by the Photographic Dealers' Association. This is as follows:—

	Developing.	Printing.
	Each	Each
3½ x 2½ (or smaller)	1d.	2d.
No. 1a F.P.K., No. 2 F.P.K. (4¼ x 2¼) ..	1½d.	2½d.
No. 3 F.P.K. (½-pl.) and No. 2c Kodak ..	2d.	3d.
No. 3a F.P.K. (postcard) and 5 x 4 ...	2½d.	3½d.

W. H. S.—We are sorry we have no particulars of the current consumption of the Cooper-Hewitt M pattern lamp, but the consumption of all mercury-vapour lamps is small. A single-tube suitable for contact printing has a consumption of 385 watts, equivalent to about three farthings per hour with current at 2d. per unit. A two-tube outfit suitable for copying has about double this consumption. The light is a very good one indeed for copying, and is less likely to show grain than any other artificial light. We are quite sure if you apply to the Westinghouse Cooper-Hewitt Company, 80, York Road, King's Cross, London, N., they will inform you as to the consumption of the M tube.

C. J.—1. The only celluloid letters we know of which can be arranged for photographic titles are those sold with the sets of announcement frames now much used by shops and others. You can get these from the Tress Company, 4, Rathbone Place, Oxford Street, London, W.1., or from a firm of shop fitters, such as

Messrs. Sage, of Gray's Inn Road, London, W.C. But the professional method of making titles is to set up the title in type and then photograph a proof. This is bound to give a very much better result than photographing solid letters, the lighting of which calls for special care. 2. The ordinary slow process or photo-mechanical plate must be used, and if developed with, preferably, hydroquinone will give a quite clear line on an intense black ground. Almost every maker has a process plate, and there is very little to choose between them.

J. E.—The best description of lens for outdoor portraiture in half-plate size is one of about 10-in. focal length and of aperture at least *f*/6, and, better, *f*/4, although the latter will be of very little advantage in making photographs of buildings, as almost always it will be necessary to stop it down. But it is very doubtful if your lens front will take so large a lens. All three makers which you mention are first-rate, but you will not be able to get a new lens either by Cooke or Ross of 10-in. focal length for the price you name. You can get this with the Aldis, and possibly an *f*/6 10-in. Aldis would be small enough to go on your lens front. Alternatively, your best course would be to state the maximum lens flange you can fit to your camera and ask a firm of dealers in second-hand lenses to say what lenses they can offer you of about 10-in. focal length, saying that you want the largest aperture, within the limit of your price, that your lens front will take.

H. H.—1. A whole-plate adapter for a half-plate camera is a clumsy kind of makeshift, and you had far better have nothing to do with it. Unless we know the focal length of your Beck lens it is impossible even to guess whether it will cover a whole-plate. It ought to be of at least 10 ins. focal length to do so satisfactorily. With suitable lenses you ought to get on just as well with a half-plate camera, enlarging to whole-plate when necessary. For a lens of anything over 8-in. focal length we should call *f*/16 a reasonable aperture, since most subjects would require stopping down almost to this for the sake of depth. 2. There is no objection to keeping used metabisulphite-hypo fixing baths in use for a day or two. Certainly most of the fixation takes place in the first bath, but prints should not suffer through receiving this first fixing in a bath which has already been used to some extent. 3. If fixing has been thorough, washing in three or four changes of water for, say, three minutes in each is ample if the negative is not to be kept longer than, say, three months.

SUMMARY.

The attention of senders of small prepaid advertisements is particularly directed to the necessity of complying with the conditions of insertion, the chief of which are mentioned on page 450.

MM. Lumière and Seyewetz, in a paper on chromium intensification, have pointed out that the process can be carried out quite satisfactorily by means of an alkaline chlorochromate in place of a mixture of bichromate and hydrochloric acid. The chlorochromate supplies the means of making a dry powder to form the intensifier by dissolving in water. The authors have further studied the chemical process of chromium intensification. (P. 451.)

Mr. Charles H. Davis, well known as a leading New York professional photographer, has very freely and frankly stated his experience and methods in the practice of at-home portraiture. (P. 453.)

In his article this week "Practicus" deals in a general way with the lines which require to be followed in undertaking work, such as the photography of workshops, etc., away from the studio. (P. 456.)

A contributor draws attention to the systematic means which may be taken for obtaining orders for portraits of babies. (P. 453.)

In a leading article we offer some simple advice to those who have a difficulty in finding for themselves the working aperture of a lens. (P. 450.)

Expedients, temporary and otherwise, for replacing a broken focusing screen are the subject of "Assistants' Notes." (P. 459.)

A paper by Mr. A. J. Newton before the Convention of the American Photo-Engravers' Association discusses the possible means of increasing production and reducing the selling price of photo-engraved blocks. (P. 457.)

Tested methods for the photographic printing of designs, etc., on wood to be hand-engraved are given in "Photo-Mechanical Notes." (P. 460.)

Extracts from a report of the British Photographic Research Association mention that the method of staining wood black or grey throughout its substance has been successfully worked out. (P. 458.)

The Ministry of Labour, after having excluded photographic studio businesses from the operation of the Retail Business (Licensing) Order, has now included them. The remedy, unfortunately, comes too late to prevent the harm which has been done many demobilised men. (P. 449.)

The Board of Trade have published their classification of photographic goods according to freedom or otherwise of importation into this country. (P. 450.)

EX CATHEDRA.

Chromium Intensification The paper by MM. Lumière and Seyewetz which appears on another page, and is a sign, we hope, that these investigators can now look forward to a resumption of their pre-war type of research, is a contribution to chromium intensification which derives its chief interest from the prominence given to the use of chlorochromate in place of a mixture of bichromate and hydrochloric acid as the bleaching solution. To the best of our knowledge MM. Lumière and Seyewetz are the first to publish the use of chlorochromate for this purpose, although we believe they are not the first to use it. According to our information chlorochromate has been used for some years past in the manufacture of the chromium intensifier in tablet or powder form for which the employment of a liquid acid is out of the question. A crystalline salt like potassium or ammonium chlorochromate conveniently serves the maker of photographic tablets as a substitute for bichromate and hydrochloric acid just in the same way as sodium acid sulphate is used as a substitute for sulphuric acid in preparations which require this latter liquid. While chlorochromates remain unpurchasable, the amateur user will prefer to make up his bleaching bath for the chromium intensifier in the accustomed way, and at the same time obtain a certain range of intensifying action by varying the proportion of bichromate to acid.

The Retail Business (Licensing) Order.

A good deal of confusion has been caused by the attitude of the Ministry of Labour in the administration of the Retail Business (Licensing) Order introduced in 1918 and designed for the very excellent purpose of protecting the interests of men who had been absent on military service. In the absence of any intimation of special exception it was natural to assume that the business of portrait photography would come within the terms of that Order, for the reason that portrait photography is taken as a business by the Inland Revenue, by the Shops Act, and by the Business Names Act. On that assumption we advised those to whom the Order applied that they came within its scope. After a time it was discovered from individual cases that, as administered by the Ministry of Labour, the Order did not apply to photographic studios, or rather applied to them only when photograph frames and other goods were sold by the portrait studio. The distinction was obviously a stupid one, since frames are sold by most studios, but, on the other hand, it provided a loophole of escape for people who were setting up portrait businesses in places where photographers, absent on military service, have been obliged to close down. As a result of a question asked in the House of Commons by Sir Rupert Guinness, we now learn that Sir Robert Horne has taken the decision that the owner of a photographic studio is engaged in carrying on a retail business within the

terms of the Order, even when his work is confined to the production and sale of photographs to private individuals. It is stated that instructions are being issued to officers charged with the administration of the Order to apply it in this sense. The amendment unfortunately comes too late in the day to remedy the injustice which has been done in many cases where men have returned to re-establish their studios, only to find that new portrait businesses had been started, through the stupid administration of the Order, in places within the absentees' circle of customers.

Intensive Hardening of Gelatine.

The particulars given in the patent specification on another page of the composition of the hardening bath, which has already been placed upon the market as the Ilford Tropical Hardener, suggest that the hardening qualities of formaline are very greatly intensified by the presence in the solution of a salt which retards the swelling of gelatine in water. Without having tried it, we should not expect the addition of even the considerable proportion of sodium sulphate to a 1:40 formaline solution to produce the remarkable degree of hardening which is exhibited by the Ilford preparation. It would seem that in some way or other a more powerful effect is produced by the conjunction of two, although it is obviously very difficult to say what it can be. At any rate the invention should prove a boon to users of plates or film in tropical countries and still more so on account of the fact that the preliminary bath may be used in conjunction with any formula of developer, and therefore leaves the photographer free to follow his own preferences in this latter respect.

Prepaid Advertisements.

Senders of prepaid line advertisements who may have had occasion to be disappointed by the non-appearance of their announcements in the succeeding issue of the "British Journal" are asked by our publishers to give their attention to the following points, failure to observe one or other of which is the cause of the non-appearance of advertisements in the great majority of cases. These points are:—

The advertisement must be fully prepaid. A schedule showing how the price of an advertisement can be reckoned correctly is sent on application.

Instruction to repeat a previous advertisement must be accompanied by the previous announcement, and must be fully prepaid.

Advertisements are not accepted by telephone or telegram.

In addition, senders of small advertisements are particularly requested to write on one side only of the paper and, whenever possible, to post their advertisement not later than Monday in the week for Friday's publication. These advertisements can be accepted up to Wednesday noon, but if the majority of advertisers postpone sending their announcements until the latest permissible time it is almost inevitable, from the exigencies of "making-up" the pages, that some require to be held over.

Imports of Photographic Goods.

A supplement to the "Board of Trade Journal" of July 31 consists of a consolidated list of import restrictions authorised by this department of the Board of Trade, 22, Carlisle Place, London, S.W.1. Articles are specified in this list, in one or other of two sections, according as they may be imported with or without licence. In the latter category (Part I. of the list) are included the following photographic requisites:—Camera shutters, cinematograph cameras, ferrotype plates, and positive papers, the latter presumably the papers or cards for direct portraits in the camera; also photographic gelatine. During the war all these goods have been upon the list of articles importation of which was prohibited by general licence, but they may

now be imported from any country, including Germany and German-Austria. The section (Part II.) of the list which itemises goods which may not be imported without licence from places outside the British Empire includes all photographic apparatus, with the exception of those just mentioned. Licences will be issued for the importation of goods to the amount of 33½ per cent. of the 1913 imports. A further class of goods coming with Part II. is "cameras fitted with lenses." No ration for these being stated, it is to be understood that their importation will be licensed only exceptionally as and when required. The schedule gives special prominence to the announcement that licences issued for goods are not available for goods of German or German-Austrian origin unless the contrary is expressly stated therein.

LENS APERTURES.

THE system of marking lenses with what are generally called f /values has now become almost universal, and practically all modern instruments have the diaphragm scale so engraved. The only notable exceptions are some American lenses of which the apertures, while conforming to the standard openings, are marked with figures which express not the relation of aperture to focal length but the relative exposures necessary. These may be recognised by the fact that starting with the largest opening, the number is doubled at each step. There is only one number which is identical and common to both systems and that is 16, which is also $f/16$ in the more usual notation. We draw attention to this because many Kodak owners who have lenses marked with the full aperture as 4 imagine that it indicates $f/4$, and consequently give much shorter exposures than they would do if they knew that in this case 4 is only equivalent to $f/8$, while on the other hand they are likely to over-expose and also to be disappointed in the depth of field obtained when using the aperture marked 32, which corresponds to $f/22$. Once this is realised it is perfectly easy to reckon backwards or forwards from number 16 when the f /values are easily found.

In the past there has been a multiplicity of diaphragm systems, while in a few cases it may be found that the apertures are incorrectly marked. We have found lenses bearing a reputable name which, purporting to have a full aperture of $f/8$, had one no larger than $f/10$, which would require an exposure of half as much again. On the other hand, we have heard of a photographer wrongly imputing misrepresentation on the part of an optician because according to his measurements a lens said to have an aperture of $f/6$ appeared to work at nothing larger than $f/7$.

It is a matter of some delicacy to ascertain the exact equivalent focal length of a lens, but it is quite easy for the most unscientific operator to obtain a sufficiently near approximation for purposes of exposure. One way is to focus an object so that it appears exactly its own size upon the focussing screen and to divide the distance between the ground glass surface and the original by four, the result being the focal length of the lens used. There is a small percentage of error in the result, but not enough to cause trouble in practical work. A more accurate way is to focus a very distant object, to measure the camera extension carefully, then to focus an object full size, and again measure the extension. The difference between the two measurements is the focal length. Neither of these methods requires any calculation, unless division by four can be so termed, and either will answer the purpose. Having determined the focal length we must find out what fraction of it is represented by any particular diaphragm opening. Here it is not sufficient to measure the diameter of the opening and to divide this into the focal length except in the case of single lenses which have the diaphragm fixed in front. With all others the convergence of the rays passing through

the front combination has to be taken into account, and in some types of lens this convergence is considerable. We have therefore to send a beam of light through the diaphragm from the back and measure its diameter as it emerges from the front lens. This may appear to be rather a difficult task, but it is really quite simple. The first step is to focus a very distant object in the usual way, next to replace the focussing screen by a card or plate of metal in which exactly opposite the centre of the lens and in the same plane as the ground surface of the glass is a pinhole with smooth edges. The camera is now taken into a darkened room and a light held near the pinhole. On the surface of the front lens will be seen a patch of light which represents the *effective* aperture of any diaphragm which is in position. The beam which illuminates the lens front emerges as parallel, and, as will be seen, this facilitates the measurements. A convenient way of carrying out this test is to dispense with the ordinary focussing screen and to make a light board of wood or very thick card which will slip into the grooves in place of the dark slide. In the centre of this a hole about an inch in diameter is cut, and covering this is a scrap of ground glass slipped under the heads of two or three drawing pins, the ground surface, of course, facing the

lens. A pinhole is now made in a small piece of metal—ferrotype plate will do—which will slip into the position previously occupied by the piece of ground glass. This pinhole may be illuminated by a small flame—even a candle answers well. Electric filament lamps are unsuitable, as it is difficult to get the filament opposite the pinhole.

As the emerging beam is parallel we can measure it in any convenient plane, and to do this we need a strip or disc of ground glass at least as wide as the lens hood. On placing this in contact with the hood or front cell of the lens we see a brightly illuminated circle, of which the diameter can be marked in pencil on the ground glass to be measured with a rule at leisure. If the whole series of stops has to be checked it is a good plan to start marking the diameters from one pencil mark, that is to say that when the diameter of $f/8$ has been marked on the ground glass, the left-hand mark should be moved up to one edge of, say, the $f/11$ opening, so that only one fresh mark is necessary. This obviates all risk of confusion at a later stage.

It need hardly be pointed out that those accustomed to use the metric system will find it advantageous to disregard the makers' designation of the focal length and to work throughout in millimetres.

CHROMIUM INTENSIFICATION WITH CHLOROCHROMATES.

INTENSIFICATION with chromium, which was first pointed out by Eder, has been the subject of various papers published by Welborne Piper and Carnegie¹, Sellors², Welborne Piper³, and, more recently, by Bothamley⁴. The formulæ for chromium intensification advocated by these various writers consist in the use of a solution of potassium bichromate with the addition of varying quantities of hydrochloric acid, or in the use of a solution of chromic acid containing an alkaline chloride.

The process takes place in two stages. In the first the image is treated by one of the above-mentioned baths, and in the second this image is developed with an energetic developer such as diamidophenol and soda sulphite or metol-hydroquinone, development being done after a washing sufficient for the removal of all traces of soluble chromium compound.

The advantages which this method of intensification possesses over the processes commonly used consist in the possibility of progressive intensification by means of a succession of the twofold operations of treatment with the acid bichromate solution and darkening in the developer, and in the almost non-poisonous character of the chemicals employed. The series of operations can be carried out without appreciably affecting the transparency of the image and without producing any residual coloured fog, so that the result of four successive applications of the intensifier allows of obtaining a degree of intensification greater than that given by the other processes, and, at the same time, highly permanent in its results.

The various writers by whom the process has been studied have recognised the necessity of using a small and exactly proportioned quantity of hydrochloric acid⁵: if the proportion of the hydrochloric acid is too great, the image bleaches in the bichromate bath, but there is no intensification produced by treatment with the developer. A result of this kind may

be ascribed to the redissolving of the chromium compounds in the excess of acid.

It may be assumed that the active intensifying agent is a definite combination of hydrochloric acid and bichromate. Piper and Carnegie¹ have explained the process on the theory of the formation of potassium chlorochromate, a powerful oxidising agent, which, according to these experimenters, converts part of the silver into silver chloride, and fixes chromium on the other portion. Bothamley assumes that the silver of the image reduces the potassium bichromate in presence of hydrochloric acid and gives rise to the formation of chromium sesquioxide, which forms chromic chromate with excess of bichromate. Nevertheless, no experimental proof of these views of the process has been forthcoming, and hitherto the composition of the intensified image has not been known.

We have observed that potassium chlorochromate (a definite compound) dissolved in water without addition of hydrochloric acid forms a good intensifier of silver images. This observation has led us to undertake a study of chromium intensification, using chlorochromates in place of the mixture of bichromate and hydrochloric acid. In the present paper we have sought to set forth the results of our observations on the following points:—

A. The substitution of potassium chlorochromate for a mixture of potassium bichromate and hydrochloric acid in the intensification of silver images.

The suitability of other chlorochromates and of analogous compounds containing bromine in place of chlorine for this process.

B. The theory of intensification with these substances and the composition of the intensified images.

Preparation of Chlorochromates.

We have prepared the potassium, sodium, and ammonium salts by evaporating a strong solution of the corresponding bichromate with a quantity of hydrochloric acid calculated

(1) The "Amateur Photographer," 1904, vol. 40, p. 597.

(3) The "British Journal of Photography," 1907, p. 3.

(4) The "Photographic Journal," 1918, No. 2, p. 53.

(5) Piper and Carnegie recommend the following formula as that giving the greatest intensification:—Water, 1,000 parts; hydrochloric acid, 1.16 = 20 deg.; Beaume, 2 parts; potass bichromate, 10 parts.

(6) The "Amateur Photographer," 1901, vol. 40, p. 399.

according to the following equation, where M represents the metal—sodium, potassium, or ammonium.

There are obtained in this way dark brown solutions which, when sufficiently concentrated, yield the chlorochromates in the crystalline form on cooling.

The potassium salt crystallises readily in fine prismatic yields of brilliant orange-red colour, much more soluble in hot water than in cold.

The sodium salt is exceedingly soluble in cold water. It is hygroscopic, and crystallises only with great difficulty.

The ammonium salt is appreciably more soluble than the potassium salt. It crystallises easily on cooling a hot concentrated solution, separating in fine scales of brilliant orange-red colour. These three compounds, which correspond with the general formula

possess the same intensifying properties as the solution of potassium bichromate and hydrochloric acid. A solution of 3 per cent. strength serves for the intensification of plates, and one of 2 per cent. strength for intensifying paper prints.

It is remarkable that the potassium salt loses its intensifying properties after having been recrystallised in water, whilst the ammonium salt retains them. This phenomenon is probably explained by the fact that the potassium salt is much less soluble than the ammonium salt, and requires for its recrystallisation a larger quantity of water. It may be supposed that the potassium salt is hydrolysed according to the following equation:

whilst the ammonium salt is not dissociated in this way.

If in the preparation of chlorochromate we use hydrobromic acid in place of hydrochloric acid, we obtain a dark brown solution which gives off bromine, and which leaves, on cooling, reddish brown crystals. These crystals, after separating and drying, were found to have no action on the silver image. Their composition has not been determined.

Theory of Intensification.

The preceding reactions may be explained by assuming that through the reducing action of the silver image the first stage of the process leads to the formation of a double chromite of silver and an alkaline metal, together with silver chloride, which is reduced to metallic silver by the redeveloper. These reactions may be represented by the following equation:

We have confirmed the absence of soluble silver from the chromium solution after intensification. The mixture of double chromite and silver chloride which would constitute the image on the completion of the first stage of the process is of brownish colour. This colour becomes more and more pronounced as the intensifying process is repeated, for the reason, no doubt, that the proportion of chromic compound increases, whilst the quantity of silver chloride is reduced. According to the equations given above, the image, after the first intensification, contains only half of the original silver in the metallic state. On a second application of the chlorochromate this half of the silver is again converted into double chromite and silver chloride. The silver chloride is reduced for the second time to the metallic state, the residual silver thus representing only one-quarter of that originally present. It will thus be seen that each successive intensification reduces by one-half the quantity of silver contained in the image in the metallic state,

and that after five successive intensifications this proportion of silver will have become so greatly reduced (to 1.32) that it is no longer susceptible to a further increase of density. These results may be shown graphically by setting off the number

Total Silver of Image.

of intensifications as abscissæ and the proportion of silver contained in the image after each operation, either as double chromites and as metallic silver as ordinates. The total quantity of silver contained in the image remains the same. In the diagram the silver in the form of double chromite is shown by the curve A A: the metallic silver reduced in course of intensification and redevelopment is shown by the curve B B. The figures 1, 2, 3 . . . 6 indicate the number of successive intensifications.

Analysis of the Intensified Image.

We have determined the composition of the intensified image by working on two series of plates which were subjected to two and six intensifications respectively in order to compare the quantities of chromium fixed in the two cases. After further washing, the gelatine film was detached from the glass and ignited, to destroy all organic matter. The residue was dissolved in boiling nitric acid and the silver in this solution determined as chloride and the chromium as sesquioxide. It was found that the total quantity of silver was practically the same in the two series, whilst the ratio of the quantity of chromium to the quantity of silver increased appreciably with the number of intensifications. The following were the results obtained:—

	Ratio of the quantity of Chromium and Silver contained in the Image.	
	After Two Intensifications.	After Six Intensifications.
Chromium, Cr per cent.	33.3	58.5
Silver, Ag per cent.	66.6	41.5

With the object of confirming the correctness of the theory which has been set forth in the preceding paragraphs, we propose to extend these analytical determinations by working on pure finely-divided silver, subjecting it to a series of successive treatments with chlorochromate, and thus determining the composition of the products which are formed before and after treatment with the developer.

Conclusions.

1. The alkaline chlorochromates serve as intensifiers of silver images similarly to alkaline bichromates with addition of hydrochloric acid or chromic acid in presence of alkaline chlorides.

2. The use of chlorochromates allows of fixing by a series of successive treatments, followed by redevelopment, increasing quantities of chromium up to a limit which appears to be reached after six successive treatments.

3. The quantity of chromium which can thus be fixed after six successive treatments is greater than the total quantity of silver forming the image. The latter appears to remain constant.

A. and L. LUMIERE and A. SEYEWITZ.

FROM STUDIO TO HOME PORTRAITURE.

[The title of this article has a two-fold significance, since the contribution is one which represents the views and working methods of one of the leading professional photographers of Fifth Avenue, New York, namely, Mr. Charles H. Davis, in practising his art of portraiture away from the studio. Unfortunately it is not possible to reinforce the advice given by Mr. Davis in the way of reproducing the beautiful examples of his work in home portraiture which accompany his notes in the "Photographic Journal of America." There the reproductions show the effects obtainable by a master of studio portraiture in the more difficult circumstances of sitters' homes.—Eds. "B. J."]

A new vista is opening for the portrait photographer. New opportunities, new scenes and new conditions await every excursion into homes, offices or gardens for the purpose of making portraits. The vogue of likenesses made in other places than studios with skylights is a growing one and is already becoming a distinct departure or branch of the portraitist's work. This is being demonstrated beyond question by the fact that some leading professionals are devoting their entire attention to this class of work and establishing successful and growing businesses in this line alone. This makes the consideration of the subject a very interesting one. It is a branch of work that requires special training, involves disappointments and heartburnings, along with the many unique and beautiful results that may be produced. It is the part of wisdom to consider the difficulties carefully, as well as to examine one's self rigorously for the qualities that make for its successful prosecution. It is unwise to imagine that the work is easy; for it is not. Compared with it, portraiture under a skylight is child's play. It used to be said that no operator (for lack of a better word) could go under a strange light and produce the best results; or, in other words, he would have to become accustomed to the varying conditions there before he could find himself and make uniform lightings and correctly exposed negatives. If this be true—and it is largely so—how much more difficult it certainly must be to go constantly into strange places and do successful work.

The factors, therefore, first of all, must be knowledge, wedded to experience, with a large amount of discrimination and tact, resourcefulness, close observation, ingenuity, patience and common sense. Given these qualities, as well as a complete photographic education, politeness, suavity and poise, there is nothing to prevent success.

These qualifications seem exhaustive, but it will be found that the successful ones possess most of them. Without these qualities I should advise the recognition of one's limitations, and continue to work in the studio, for a large measure of success will only come to those whose personal endowment and ability equip them to master the difficulties and disappointments with which the path is so plentifully beset. In passing, let us note that patience and a capacity for hard work are largely matters of self-control. These qualities are very necessary, and may be cultivated. I speak from experience, and know. I have been lauded by clients for infinite patience, but I know in my own heart that I have little of this quality; but with determined self-control I have produced the impression of having it, and perhaps this amounts to the same thing.

Another qualification which is very important is the ability to pose the figure gracefully and give due attention to the arrangement of the hands. If the charm of home settings is to be preserved, the figure must be shown. The environment found in the home will make the picture interesting and valuable.

The phrase "home portraiture" should mean something more than merely a portrait made at the patron's home. It should mean something beyond the stereotyped head and bust representation which has become the major type of portrait produced by the rank and file of the photographic profession. This style of portraiture has degenerated until it has now

become a sort of map of the sitter's features, often freakishly and spottily lighted by electric additions to daylight, sometimes over-obscured or befuddled by the misuse of soft-focus lenses, and further distorted by curiously wrought backgrounds supposed to imitate the masterpieces of portrait painting, but really doing violence to their memories and traditions. Since this style took possession of some of our high-priced specialists, a sort of picture has prevailed that may be made anywhere, and is actually produced in any old place, and it is a sort of portraiture that does not reflect a large amount of credit upon the maker or lead to a higher plane of work. The writer hopes, through the growing vogue of "home portraiture," to see a return to sanity in picture-making, and more use of the figure, and once more behold a product that shall not only portray the subjects as they are, but shall, in addition, give them the individuality of their own surroundings. Thus Mr. A.'s portrait shall become quite different from that of his neighbour's, so that Mr. B.'s portrait, when perchance they exchange, will not be identical except for a difference in physiognomy. In short, let us make pictures of people at their homes that shall proclaim them to be at home and at ease among their own individual things.

With this desirable feature in view, the folly of always putting the subject in a predetermined pose or fitting them into a certain style of lighting becomes quite apparent.

My outfit for outside work consists of a 10 by 8 standard make of camera, called "home portrait" by the manufacturer. It uses double holders for plates or films. It is very light, and all the movements, which comprise double swing back and rising and falling front, are quickly and conveniently made by thumbscrews. There is also provision for adjusting the entire front sidewise on the base. The bellows is square, and the front board is large. I use a Thornton-Pickard roller-blind shutter with positive cable release. This shutter can be set for time or instantaneous, and is absolutely reliable, and makes little noise. Mine is attached at the back of the lens outside of the camera, and is removed and placed inside for carrying.

The whole packs closely and is carried in a case with three holders, and lens. For additional holders I have a separate case. The entire outfit when closed for carrying is in three parts—camera, plate-holder case and tripod. The holder case is carried by a shoulder-strap, leaving the hands free for camera and tripod.

There are very convenient but expensive home portrait outfits on the market. The length of one's purse must regulate this outlay. It pays to own a convenient and well-made outfit, and the purchase of such is really an investment. Besides, your client is impressed by a good-looking apparatus.

I use a standard centre-leg tripod of wood that folds compactly. This style of tripod is rigid, can be raised and lowered, has a tilting top, is readily moved about, and will stand anywhere securely. The character of the tripod is of the greatest importance. Much time and temper are lost with the ordinary folding type. It slips at the most inopportune moment, or when engrossed with the subject a chance movement may trip one leg, with disastrous results not only to one's own feelings and temperament, but to those of the sitter. Then all has to be done over again. If the camera has not

been smashed or other minor damage done, much damage has accrued to other things concerned. Not only has one's own equanimity been upset along with the camera, but the subject's already tense feelings are tightened, and there is, to say the least, the devil to pay. Consequently, a few dollars invested in the centre-pillar, spreading-leg, adjustable tilting-top variety are well spent, for such a tripod will stay put and remain constant upon the smoothest wax-polished floor—where perhaps angels fear to tread. So much for tranquillity and certitude. This type is manufactured by at least two different concerns.

As to the lens, for all-round use I have found a Cooke Series VI., 10 by 8, 13-inch focus, $f/5.6$ the most satisfactory for home portrait work. The focal length is not ideal—a longer focus would be an improvement in many ways—but as one has to consider limited working spaces or carry several lenses, the above seems to be the most desirable. It gives a minimum of distortion even on large heads, and it has brilliancy, ample speed, and, if wanted, critical definition. Not even the Hun makers, perfect as their products are, have anything on the English Cooke; in truth, I am confident that it is quite an unequalled product. Of course, a battery of convertible anastigmats would be the criterion of luxurious perfection, but this again involves an extra weight to carry, and I have been in few situations where I felt the need of anything beside my perfect Cooke, which gives, in addition to its exquisite definition, a range of diffusion that enables one to verge on soft-focus effects with every degree between that and positive sharpness. This lens is provided with attachments for cords, enabling one to regulate the diffusion while observing the ground glass; and this I find in practical use a very desirable feature. There are plenty of good lenses, however, and more depends on the user than is generally recognised by those of scant experience. The American-made Velostigmat, 8 by 10, $f/4.5$, is well spoken of, and its 12-inch focus is satisfactory. I would not advise a shorter focus lens. An inch or two more will give far lovelier results, as the perspective is less violent.

I am usually provided with plates or films for eighteen exposures, and, if necessary, an extra package of plates or films, which can always be changed on the spot in any dark closet in the home. I do not find a safe light necessary for changing. In addition to the above, I always carry a twenty-five foot length of strong cord, about a half-dozen spring clothes-pins, a few brads and small nails, and a few sheets of white tissue paper. I always find a reflector in a sheet at the home, and unless I know beforehand that the walls of the home are impossible photographically, I never carry any sort of a background. Thus equipped, I generally am able to secure satisfactory results.

While on the subject of equipment and materials I wish to record the fact that the new portrait films are ideal for home work. They possess qualities besides lightness and freedom from breakage. Halation is reduced to the minimum, and they seem to have both latitude and speed. They are coated with a very superior emulsion. It is to be hoped that the present high prices for them may be somewhat reduced in the future. This is the principal objection to their more general use.

I do not carry or recommend the use of an electric light except in emergency cases. It savours too much of taking the studio to the home. An adequate equipment for artificial lighting would need a truck or at least an automobile. The use of electric lights is probably the reason for much of the hard and contrasty home work we see displayed. It is well to supplement daylight by artificial, but I do not find in practice

that it is necessary to carry an electric equipment. The new flash lamps seem to be successful, but cumbersome. A good open flash that spreads along a channel of metal and sets off by a trigger and cap is occasionally very useful. Employed with skill, its results are good. I have often helped out with a small flash, and no trace of its use can be found in the negative. Of course, it must always be fired so that no direct light from it can enter the lens. A lamp of this kind is very inexpensive, and can be carried in the pocket.

The figure should be made to play a more important part in home portraits, giving them real value as human documents, and it should usually be possible with the sitter "at home" to include something of their surroundings, something suggesting the subject to their intimate friends, who are the ultimate recipients of personal photographs.

There can be no doubt regarding the tremendous advantage this growing opportunity presents to the photographer who is alive to its great possibilities and able to surmount the difficulties. Always confronted with new conditions, new surroundings and new light effects, he should give full play to his originality, and produce work of infinite variety and charm, reflecting the changed conditions rather than seeking to knock every portrait and condition down to the dead level of studio mediocrity and sameness. He is no longer bound and trammelled by a skylight and its few changes of lighting effects—by a few pieces of furniture and accessories that must be used again and again, day after day, until, dispose them as he may, they appear and reappear in his work *ad nauseam*. He has at hand a great variety of accessories and furniture all waiting to be fitted into his portraits, which, if employed judiciously, and recorded with simple truth and beauty, will make his work instinct with life and character and give it those indefinable qualities which differentiate each person from every other, which may be summed up in the single expression of "personality."

I venture to advise that any disarrangement of furniture, curtains, or pictures be religiously restored just as found. The housewife and her servants will appreciate your care and thoughtfulness.

In proceeding to make negatives, the first thing that should be guarded against is a violent or contrasty lighting. The sitter should be placed at some distance from the window, certainly six or eight feet, sometimes more, depending on the area of the window. If the window receives the direct light of the sun it should be covered with white tissue paper. A few pieces of gummed paper should always be carried, as it is very useful to fasten the tissue together and suspend it in the window. A good trick is to pull down the window shade and attach the tissue to it. By the simple process of allowing the shade to go up to its full extent the tissue will be carried up smoothly and the window covered. If the light is very brilliant it is a wise plan to interpose an additional tissue paper screen between the window and the sitter. This may be fastened to a stick or a broom handle, and there is generally someone willing to hold it where wanted. A small clothes-horse from the kitchen will be found useful for this purpose. By this screen the light on the sitter can be toned, regulated and controlled. Letting a little light shoot in behind this screen will give a beautiful roundness. In case a Rembrandt or edge lighting is desired, the screen may be increased in opacity by a newspaper so that the light can be manipulated perfectly and the screen will still pass enough light to avoid hard shadows. It will be found that the tissue window diffuses the light very greatly and becomes the *source* of light.

Use a reflector, but do not overdo it. A sheet held by a member of the family or supported on a cord fastened across

the room is satisfactory. When no assistant is at hand, or no one can be impressed, I use a long cord (which I always carry), fastened to any convenient object at each end. The sheet may be suspended just where needed by the use of spring clothes-pins. The reflector is a real necessity nearly always, though many spots may be found, such as a corner with windows on each side admitting light of different degrees of strength. One window is sure to be brighter than the other, and if this condition is taken advantage of the subject gets a round lighting with soft shadows without a reflector. Here enters the faculty of observation and of adapting one's self to conditions.

In working in homes it is always best to select a room with light decorations, as the general illumination of the apartment is greatly enhanced by the reflections from light walls. It is frequently possible, under light decorative conditions, to avoid the use of a reflector. Sometimes a pier mirror is available as a reflector, and as this gives greater brilliancy, one must be on one's guard against unpleasant double lighting effects. A mirror reflects much more light than a white cloth, consequently it must be kept farther away from the sitter.

When a movable mirror is available many attractive variations on the simple portrait may be made by its use. Mirror pictures are justly popular with the ladies, and if the subject admits of a profile as well as a front or three-quarter-face pose, very picturesque and beautiful results may be produced. The mirror can be so placed that the reflected image is nearly in the same plane as the face proper, thus getting a sharp reflected image. Sometimes it is pleasing to let the reflection be only an accessory in the picture, in which case it is admissible for it to be out of focus to a certain extent. The head may be posed often without much regard to the reflection, producing an interesting and pleasing result. Often it may be necessary to reduce the lens aperture considerably in order to make both images reasonably sharp, and unless the light is abundant this involves a longer exposure, with danger of movement. I advise experiment with a mirror to find just the right angle to bring both images into focus at full opening. Short exposures, or the shortest possible, are always advantageous in order to record good expressions.

Care must be taken to avoid the inclusion of unpleasant objects in the mirror. This can be overcome, however, by having a plain cloth of almost any colour held where the mirror will reflect it with the sitter, but the tone of the background shown in the mirror should be a distinct contrast for the best effect. For mirrors on walls, oval shapes are the most desirable, because they are not noticeably altered in shape by the position of the camera. A very attractive effect may be produced by placing such a mirror about three feet from the window on the same wall. By manipulating a sheet diagonally in front of the window enough light is thrown upon the sitter to give a beautiful effect. In making this sort of a picture the other windows in the room can be used to give general illumination. The lens must be carefully screened to prevent any direct light reaching the plate and producing fog. Always bear in mind that the lens is also a window, and that it is easy to get more light than picture on the plate.

In conclusion, let me say that in the well-nigh universal gradgrind of our profession of photography there is too great a tendency to do things in the easiest way. It is, as before mentioned, much simpler to avoid figure poses and to blot out (scrape out) undesirable backgrounds and put in others by the

use of the ground-glass substitute and stump work, creating something that is false, inappropriate, and absolutely in-artistic, and the defence is that the customer likes it. It is infinitely better to find a suitable place for the portrait in the home and leave the natural result untouched, for by so doing not only is the portrait made appropriate, pleasing and artistic, but the result is achieved without additional labour and expense—surely a consummation devoutly to be wished. But—and here comes the rub!—this involves care, painstaking skill and resourcefulness on the part of the photographer. These desirable qualities should be more generally cultivated. I hope that this may be realised through the production of figure portraits in the home, for by just these virtues are better pictures to be made.

Furthermore, I believe in educating the client as well as ourselves. Let us in our studios emulate the example of a famous printing house said to do the best catalogue printing in America. In the anteroom through which visitors and customers must pass are exhibited in show cases many examples of early masterpieces of printing. This exhibit, says Henry Lewis Bullen, a great printing expert and authority, creates an *expectancy* of quality and lends dignity to the printing house. If we photographers would collect and display masterpieces of drawing, painting and sculpture, done by photography and in plaster, of faultless and recognised merit, would not they have a similar effect on our customers and visitors? It would at least tend to show that we had ideals, and in educating the customer we would likewise educate ourselves, making easier of accomplishment many things we now pass over as quite too much trouble to be considered. It has been well said that if we are to do beautiful things we must live in an atmosphere of beauty and refinement, so that our habit of thought tends that way. A beautiful environment has a potent influence on workers of every degree. The mind thus becomes educated, and better work is the unconscious result. Let us have ideals, and work toward them.

Home portraiture is an avenue of escape from the hum-drum stereotyped of the studio. Let us therefore grasp these delightful opportunities and try to accomplish more original and beautiful results. Every sitting in the home is an adventure, fraught with wonderful possibilities. The way is an untrammelled one. Keep your minds open for new effects. See with your minds more than with your eyes, and your results will often surprise yourselves. These things are of vital interest to those among the profession who hope to see the photographic portrait business carried on prosperously and pleasurably by all who are engaged in honest endeavour. Wherever home portraiture fails to be honoured and sought after and well paid for, the cause is to be found in the limitations of the photographers themselves. Home portraiture is an art that requires intelligence and ability above the average to make it really successful. The mechanics and processes of the art are very efficient, and there is no secret as to methods; its failure is in those who use the machinery and methods. The route to eminence is through the study of inspiring works of art. There is no other way. Rudolf Eickemeyer achieved his great reputation and incidentally his great collection of medals and other honours by persistent application, study and hard work. Edison says that "genius is 10 per cent. inspiration and 90 per cent. perspiration"; in other words, the capacity for taking infinite pains.

CHARLES H. DAVIS.

THE ENSIGN QUARTERLY of Messrs. Houghtons, Ltd., which is just issued, in its address to dealers, strikes a confident note of the future of the British photographic apparatus trade, even while it asks for patience on the part of dealers and a recognition of the difficulties of the time. The little journal invites dealers to make

the personal acquaintance of Mr. Stanley Houghton, now the firm's sales manager, and it gives some examples of the distinctive and attractive advertising which Messrs. Houghtons are using in the lay Press in accordance with their programme of popularising Ensign photography.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
 The Camera and the Lens (Jan. 10).
 Managing the Sitter (Jan. 17).
 Backgrounds (Jan. 24).
 Studio Exposures (Jan. 31).
 Artificial Lighting (Feb. 7).
 Printing Processes for Portraiture (Feb. 14).
 Studio Accessories and Furniture (Feb. 21).
 The Surroundings of the Studio (Feb. 28).
 Studio Heating and Ventilation (March 7).
 The Postcard Studio (March 14).
 The Printing-Room (March 21).
 About the Reception Room (March 28).
 Home Portraiture (April 4).
 Portable Studios (April 11).
 Copying (April 18).

Handling the Studio Camera (April 25).
 More About Lenses (May 2).
 Enlargements (May 9).
 Advertising the Studio (May 16).
 Mounts and Mounting (May 23).
 Business Methods (May 30).
 Photographing Children (June 6).
 Portraits of Elderly People (June 13).
 Something about Lenses (June 20).
 Hand Cameras for Professionals (June 27).
 The Dark-Room and Its Fittings (July 4).
 Plates and Their Work (July 11).
 Apparatus Repairs and Renovations (July 18).
 Posing the Head (July 25).
 Intensifying Portrait Negatives (Aug. 1).

WORKSHOP JOBS.

The photographer whose lines are cash in a small town cannot afford to specialise in any one branch of work, but has to be prepared to undertake any commission which comes in his way. In London and most of the great centres there are specialists in photography as there are in medicine, engineering, architecture, and these keep pretty strictly to their own lines. The man who has attained a position as a delineator of society beauties does not seek a job to photograph the interior of a factory, while the technical man who is au fait in engineering and architectural work keeps equally aloof from making flattering portraits. The "country mouse" has, however, to be a good all round photographer, for he cannot afford to decline jobs which may make all the difference between a bare struggle for existence and comparative comfort. This being so, he must pay great attention to what I may call the minor technics of his work, for on these his success in branches other than portraiture must mainly depend. To be a successful portraitist, a man must have natural genius, but for technical work the genius that arises from "an infinite capacity for taking pains" is the kind required.

Factory and workshop photography, comprising interiors and exteriors of buildings, as well as single machines and other constructions, is a class of work which every general practitioner is called upon to do from time to time, and if the prints are to compare on equal terms with those made by specialists, a considerable amount of study as to the best apparatus and conditions required will be necessary. The photographer must also be able to point out to his clients in advance whether certain photographs can be attempted with any reasonable chance of success, but must not put difficulties in the way unnecessarily. I have always found customers of this class very reasonable to deal with, and ready to accept any suggestion which may lead to a successful issue, much heartburning being avoided by having a clear understanding before starting on exposures.

To give a clearer idea of what I mean, I will suppose that an engineer sends for me and says that he wants a series of views of his workshops taken. My first action would be to ask him to come round the building, and to point out what were the especial features of interest in each department, and the angle which it was desired to include. Also, I should at this stage arrange if possible for any touching up or preparation of such articles as would be improved by a little judicious "faking." This should, if possible, be arranged before the

actual time fixed for the work, so that the photographer need not waste valuable time while these preliminaries are being attended to. The client will often be willing to remove benches or even small pieces of machinery if they would interfere with a good view of the shop as a whole. Windows may require blocking up, and sometimes the machinery itself may require a little treatment such as dulling bright parts, painting other parts a lighter colour, and general tidying up.

Extremely wide-angled views should be avoided if possible, as the unnatural-looking perspective which results is often very unsatisfactory. Wheels which should be circular appear elliptical, while cylinders assume shapes which no engineer would tolerate. If, however, such views have to be made, care must be taken so to choose the point of view that these effects are reduced to a minimum. It must always be remembered that artistic effects of light and shade are not appreciated in commercial work if they exist at the expense of detail, and, therefore, one must be careful to give full exposures so that no large expanses of unfilled shadow are left in the negative. An exposure meter is a great help to the inexperienced, and as the standard tint takes rather too much time in most workshop interiors, it is advisable to use a "studio" or "snapshot" dial by means of which a test can be made in a reasonable time. Many years ago a very experienced technical photographer, Mr. J. A. Harrison, who had himself been an engineer, devised a little camera on the photo-button model, using one inch squares of the same brand of plates which were to be used for the large negatives. The lenses had an aperture of $f/4$, and the exposures were developed in the camera. This was a perfect exposure meter, but somewhat cumbersome as compared with the modern instruments.

The lenses should be carefully selected, and anastigmats will be found preferable not only on account of their superior marginal definition, but because it is easier to arrange the view on the screen at, say, $f/8$ than it is at $f/16$, which is the maximum aperture of the older types of wide-angle lenses. The final focussing should be done with as small an aperture as convenient, and it is helpful to have a card or two printed in bold type which can be held in different places by an assistant, so as to be sure that everything is well in focus. A focussing eye-piece is generally desirable, and the focussing cloth should be ample in size, and quite opaque, so as to make the most of the feebly-lighted image. If it be found impossible to get sufficient depth, the definition at the farther end of

the room should be sacrificed rather than that in the foreground, as this gives a much better effect in the print. As a rule, a rather high standpoint should be chosen, the lens being six or seven feet from the floor. This gives a better general view, and prevents one machine or article from blocking out another. It also allows of a larger aperture being used, as it necessitates the camera being tilted down to include the foreground; then, as the top of the camera back has to be swung *outwards* to rectify the vertical lines, it helps to bring the foreground into focus, exactly the reverse effect of that obtained when pointing the lens upward, which necessitates the use of the smallest stops. The high position also minimises the necessity for raising the front—a rather important advantage when using a wide-angle lens to the limit of its capacity.

As the exposures are necessarily long, it is advisable to use rapid plates, as it makes a considerable difference in a day's work, whether ten minutes or half-an-hour is needed for each exposure. In well-lighted shops it is often possible to get exposures short enough to include the workmen at their benches or lathes, the exposures being then anything from 15 seconds to a minute. A flashlight fired at the end of such an exposure will often greatly improve a rather dark foreground without interfering with the general daylight effect. Plates should always be backed, and if there are any windows directly facing the camera they should, if possible, be covered up for part of the exposure. This can often be done from the outside by hoisting a sheet on a couple of poles.

It may be thought that the foregoing instructions seem to tend rather in the direction of fussiness, but nothing that will help to secure a good result should be overlooked. It is the man who walks in and takes the place "just as it is" who runs the risk of having his work turned down. Circumstances

may be favourable, and the job may turn out well without much trouble, but it is in difficult work that a reputation can be made, especially if another photographer has previously failed.

As a rule, the prints should be made on glossy paper, as not only does it show detail better, but the surface keeps cleaner. Personally, I still prefer P.O.P. for such work, toning to a good purple black. It is also easier to shade and fake in printing, as the effect can be seen while printing is in progress. For reproduction glossy bromide is often required, and for some negatives is to be preferred, as softer prints can be obtained by giving full exposure and short development. This may give a bad colour to look at, but one which will reproduce well. Despite a general impression to the contrary, hard or brilliant prints are not required for process work. The engraver can modify the contrast to a considerable extent, but he cannot supply black patches with detail.

A point which is often overlooked is that, as the size of a direct negative is increased, the difficulty of securing adequate depth of focus is increased in a greater proportion. This is easily realised if we consider what is done every day with the little fixed focus cameras with apertures of about $f/12$. The photographer who works a 15×12 camera will find that he hardly gets equal depth at $f/64$. I had recently to make a series of 15×12 prints showing men at work, some of them fairly close to the camera, and others far away; $f/64$ was impossible; therefore, I used a half-plate camera fitted with a 4-in. lens, and secured sharp negatives at $f/22$. When enlarged to 15×12 , the general sharpness was far better than that which could have been obtained in any other way.

PRACTICUS.

HOW TO INCREASE PRODUCTION AND REDUCE SELLING PRICES OF PHOTO-ENGRAVING.

(A paper read before the Convention of the American Photo-Engravers' Association, June 20, 1919.)

WE are all in business to make a profit, and it is a tacit assumption that we must maintain at least the same profit if we reduce the selling price; in fact, if the aggregate profit is not to be greater there is little object in either increasing production or reducing selling price, unless the photo-engraver wants to benefit his kind by providing abundance of engraving without hope of any extra reward for his efforts.

Highly profitable businesses can be divided into two kinds, the common object produced in huge volume and the extremely rare object which has a monopoly value because of its scarcity. The Ford motor-car is an example of the first. Because of its quantity production the profits are large, although the highest wages are paid and the best material is used. The profits on each machine are probably not proportionately so much as on the Rolls-Royce car, but in the aggregate they are enormous. The other type of profitable business is the antique dealer, who, if he has a suitable market, can sell his treasures at a profit of thousands per cent. Now there is no chance of photo-engravings coming into the latter category, so we are confined to seeing how nearly we can approach the volume production type.

As I stated in my paper on "Technical Requirements for Profitable Photo-engraving," read at the St. Louis Convention, the first necessity for profitable business is plenty, but not too much, work all the time. Every engraver knows that if he makes an average profit with an average volume of work, when he doubles the volume his profits will increase more than proportionately; if he halves his volume, not only will his profits vanish, but a serious loss be incurred. This volume must be evenly distributed; where too much work is almost as bad as not to have enough; everybody is worried to death, and work is often poor as a consequence.

Unless we have volume, therefore, there is no chance of reducing costs or reducing prices: if you have volume both would be practicable. How can the engraver get a bigger volume of work? By inducing further consumption. How much further can consumption be increased? and will the increased consumption be supplied by the firms already in the business? If not, that is if fresh firms are to be started, there will be no increased volume for those already in business, and therefore the cost of production will remain the same. It is useless to talk about technical improvements or organisation of staff unless you have a volume of work that will enable you to instal time-saving methods and the very increase of work with a staff that is willing to co-operate will itself cause quicker methods to be adopted. Economy in production is almost entirely a question of subdivision of labour and specialisation, and this can only be accomplished where there is a large volume of work and a staff of specialists to handle it in smaller and smaller stages.

It is unlikely that we shall see specialisation of the various fields of photo-engraving and each firm undertaking only the work for which they are exceptionally qualified. This might lead to a lowering of cost of production, but, as things are now, it is difficult to see that a very great lowering of cost can be expected. If we have to handle all kinds of work well, all we can do is to get men of the highest skill, and endeavour to see that they do their work in the most efficient way—not a very easy thing, for a highly-skilled man often insists upon doing his work in his own way, however wasteful, and if you want him to do it differently he is no longer skilful, but tends to spoil everything.

It is no doubt possible a certain amount of extra production could be obtained even by present methods if we had complete co-operation of staff and willingness to speed up, but this cannot be

expected unless the men have some further incentive than their regular weekly wage, and therefore some extra payment for extra product must be provided.

This is a difficult thing to work out for photo-engraving, but, nevertheless I believe it can be done, and, in fact, must be done if we want to reduce costs of production. The men would have to be guaranteed their regular wage in any event, and then all over a certain standard of production would be paid for extra, and they should be allowed, or invited to have, some voice in the fixing of these rates; that is, you must govern with the consent of the governed. Their payments should take the form of cash, paid as soon as possible after the work was completed, so that the incentive and the reward are not too far apart.

Careful track of costs must be kept if we are to know which kind of production pays and which does not pay, so that the latter may be eliminated. Overtime must not be worked without it being distinctly understood that there is an extra charge, to cover its cost. Duplicates should be encouraged. Cash payments must be required, as long credits and bad debts are part of the present cost of production.

As far as I can see, there is small prospect at present of costs of production being reduced, but I have stated what I think are the necessary conditions. If these conditions can be complied with, there is no reason why costs should not be lowered, and, if the engravers wish to do it, selling prices reduced; not otherwise.

A. J. N.

THE BRITISH PHOTOGRAPHIC RESEARCH ASSOCIATION.

The following are extracts from the recent report of the Director of Research, Dr. R. E. Slade:—

A wide programme of research has been drawn up and preliminary experiments made on a large number of the subjects mentioned in the programme.

The history of photographic science and industrial development shows that since the publication in 1891 of the researches of Hurter and Driffield, practically no new methods of attacking the problems of photography have been introduced. Many workers have improved and worked out further details of the old-established methods, and very considerable advances have been made, but the time now seems ripe for entirely new methods of photographic research. The Association is using all the means at its disposal to initiate such new methods, and is making progress in this direction.

As is laid down in our programme, we are attacking problems by investigating the fundamental principles by any or all of the latest scientific methods. We do not generally make use of what I may call empirical methods guided by scientific knowledge, because this is what is being done in the factories, and the factories are in a better position to do this than we are. It is, indeed, by these empirical methods that the photographic industry has obtained its present excellent position. We believe, however, that we are taking a long-sighted view, and that we shall open up new fields in which we shall use all the methods we can, including empirical methods, to get results of technical and industrial value.

We have made some experiments on gelatine, which, though not suitable for publication, will be of great use to us in future work. Progress has been made in our investigations of photographic emulsions, and we shall shortly have a communication on this subject to circulate to members concerned.

I might mention here that we have succeeded in staining wood black or grey right through. This black wood, which was made in Germany before the war, is used by manufacturers of cameras and optical instruments, and the grey wood is used for picture frames and furniture. Our process, for which an application for a patent has been filed, should be quite suitable for use on a large scale, and quite economical. This was a research carried out entirely by empirical methods guided by our knowledge of the methods used in dyeing cotton. As we are not immediately interested in the further development of dyeing wood, there is no reason for us to find out why the methods of dyeing cotton cannot be directly applied to wood. Perhaps some day the furniture manufacturers of this country will find it to their interest to investigate this problem.

We have already published two communications from the laboratory in scientific journals. They are:—

“Contrast and Exposure in X-ray Photographs through Metals,” by Dr. R. E. Slade, D.Sc., F.I.C.

“The Fundamental Law for the True Photographic Rendering of Contrast,” by A. W. Porter, D.Sc., F.R.S., and R. E. Slade, D.Sc.

Results of research, whether theoretical or experimental, which are of general interest and not of immediate use for application to specific problems of the industry, are published at the first opportunity, to increase knowledge in photographic science generally and to induce other workers to devote their attention to theoretical problems.

As an example of the advantage to be gained by publication, I may say that the first paper mentioned above caused a good deal of discussion in certain scientific circles, and as a direct result I combined with Professor A. W. Porter, F.R.S., in the production of the second paper, which clears up an important point in the fundamental theory of the photographic process, a point which Hurter and Driffield attempted, but failed, to elucidate.

H.M. THE BABY.

The photographer, possibly more than any other business man, has reason to know that fond parents are never tired of seeing representations of their offspring. The amateur knows also, and suffers acutely from the voracious appetite for “snaps” of baby. The power of H.M. the baby to loose the purse strings is truly remarkable. But in this article we are not concerned so much with methods of exploiting the dear infant once it is in the studio as with a method for getting the little cherub there.

First Catch.

In this connection it may be remarked that, like the hare in the cookery book, baby must first be caught. Naturally baby must be caught young, the younger the better for our purpose, as will be seen. How to do it—that is the question. The plan sketched out below may be new to many readers, but its potentialities from the point of view of business are great.

A Systematic Record.

Some most valuable information is presented free every day to the photographer who cares to look for it. It is fortunate for him that despite the age-long repetition of the occurrence there are still many thousands of parents who like to announce the circumstance of the advent of another “little stranger” by putting a notice in the Press. Any enterprising photographer who cares to make and conscientiously keep records of these announcements should be able to derive profit therefrom. The idea, in a nutshell, is to note the name and address, and in due course—when there is something a little more tangible than frills and bubbles to see—invite the proud parent to have the baby photographed. Somebody will have to photograph that baby—the thing is to see that at any rate you make a good bid for the business.

Looking Ahead.

But the idea runs further than baby's first photograph, and the value of such a record will increase as time goes on. Suppose, for example, the reader has made the first photograph, during the course of which business he has, like a wise man, found out the child's Christian name, and so on. The record is amplified, and on the occasion of the first birthday a suggestion can be sent along that baby be photographed on the first birthday, and after the first on every birthday as it comes along, and while the sitter remains in the district. At first the interest of the parents should be strong enough to keep the habit alive. Later the young person's interest in him or herself should help the photographer to establish the desire to preserve a record of looks at each birthday. Alfred Russell Wallace deplored the fact that people did not have themselves regularly photographed on their birthdays or at other stated times from infancy to age, as such a record, he said, would be of great value, besides providing interesting evidence of the moulding of feature and expression under the hand of time.

How to Do It.

The reader who is unacquainted with modern devices for simplifying business may see visions of much work in the keeping of the records suggested. But it is really quite a simple matter. The thing may be done in a variety of ways, and each may do it as he chooses. But those who wish for advice may be recommended to try a simple card index. The size of the card may be 5 by 3, which is a standard size, and a single-drawer cabinet may be made or bought that will hold 1,000 cards. First make twelve sets, each numbered 1 to 31 in the right-hand corners; these we may call daily cards. Then make twelve guide cards—i.e., cards with tabs projecting above the ordinary cards—and write the names of the months on these. Now put one set of numbered cards behind each month card. The records can be made either on the numbered cards, or a separate card for each entry may be kept behind the numbered cards; and in addition to name and address, record made of invitations sent and business resulting. The record will, of course, consist of name and address of parents (to be supplemented later by child's Christian name), and date of birth. Each separate card should have the month and date inscribed on the top right-hand corner. Here is a convenient way of doing it:—7819 means August 7, 1919. If that card is removed from the index, then it is easily replaced in its proper position by reference to the number on it.

Using the Records.

It will be seen that the records may be used at once, and also year by year as the dates come round. The first attack would naturally be made within a few weeks of the record being made. Thereafter the thing would be worked by a scrutiny a week or two ahead of the dates, so that the invitation should reach the prospective sitter just as the birthday looms on the near horizon.

Avoiding Blunders.

Care must, of course, be taken to prevent an invitation being sent that might reopen a wound caused by the death of the child. Births and deaths announcements must therefore be studied together, and a second index or record in a book, in alphabetical sequence of names, is necessary to enable the record to be struck out or removed in case of death or removal of the family. To make assurance doubly sure, judicious enquiry of the milkman, the baker, or other daily visitor to the house is recommended before the invitation is actually despatched. Or it may be sent by hand by an intelligent bearer, who will enquire before actually leaving the note. Reasonable care will prevent any unfortunate incidents of this sort.

M.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Replacing a Focussing Screen.

I SUPPOSE that most of us have at one time or another had the mortifying experience of smashing a focussing screen. At the best, this is most annoying; but when it happens far from the studio, with an urgent job to be done, it becomes a positive disaster. However, things are rarely so bad as they seem, and a little ingenuity will usually find a way of repairing the damage. So, perhaps, a brief review of the means at our disposal for replacing a breakage may prove of interest. We will divide the subject into three sections:—

- A. The provision of a permanent screen.
- B. The provision of a temporary glass screen.
- C. The provision of a substitute when glass is not available.

To take section A first. The provision of a permanent screen may be necessary either to replace a breakage, or to improve on an existing screen, and certainly many screens in regular use are open to great improvement in the matters of fineness of grain and translucency. Unless one has compared two screens under similar conditions, it is almost impossible to realise the added ease in working given by a really fine screen.

A very satisfactory screen may be prepared by grinding two glasses together with knife powder. The powder must be slightly damp,

and it will then be found to grind very slowly, but with a beautifully fine grain. Emery powder is often recommended for this process, but there is the danger of getting a coarse grade, and, although it is certainly quicker to "bite" the glass, I do not think that the result is so good. Personally, I have found nothing so good as "Wellington" knife polish. Incidentally, it should be mentioned that it is no good trying to "rush" the grinding process, as the usual result is a smashed glass.

Glass may be given a very fine matt surface by etching it with an acid, but it is hardly the job for anyone but an expert to undertake. This is the method by which most of the finest commercial screens are prepared.

When an exceptionally fine screen is required, it is best to give up the idea of matting the glass itself; the best way is to use a fine-grain dry plate (unexposed, of course), and give it a slight "red fog." This may be done by developing it, in the dark room, of course, in a ferrous citrate developer to which ammonia has been added in sufficient quantity to make it slightly alkaline. This gives a beautiful screen, which is unbeatable for any delicate work. As ferrous citrate has gone out of use, and the average man has not time to make up new solutions, it may be as well to give another way of getting a somewhat similar result. Slightly light-fog a plate; for instance, expose a slow plate for five seconds at 20 ft. from a burning match, and then develop fully in any non-staining developer. To get the best results by this process it is essential that development should be full, so the exposure must be adjusted to give the correct density. If a large screen is wanted it will be found best to use a smaller plate of the same brand to experiment on, as, at first, it is difficult to judge the required exposure.

A very fine, but somewhat delicate surface for focussing may be got by flowing on to glass a mixture of: white wax (¼ oz.) in ether (1 oz.) in the proportions indicated. This dries quickly, and gives quite a good surface; but, unless protected by a varnish, it is very liable to mechanical injury.

We will now pass on to section B. Temporary screens may be prepared in dozens of ways, but one of the best is by applying ordinary matt varnish to glass, or, if matt varnish is not at hand, ordinary negative varnish may be used. It should be mixed with about an equal quantity of water, in order to get a matt effect.

These give quite satisfactory screens, but often varnish is not at hand; anything that will leave a thin film on the surface of glass may be used. For instance, flour paste, and photographic mountant may be smeared over the glass, or putty or Plasticine may be daubed on to it. The trouble with these make-shifts is to get a fine grain; but, with care, a decent surface may be prepared.

Quite a good screen can be made by soaking a sheet of tracing-paper in glycerine, or even, at a pinch, in water, and squeezing it on to glass. This is rather a messy process, and it must, of course, be used before the paper becomes dry; but while it is wet it is remarkably efficient.

In cases of great urgency, an unexposed dry plate may be used as a screen without any preparation, but even the thinnest emulsion stops so much light that focussing is very difficult. Still, it is often a quick way out of an awkward position. Also I have focussed on a negative fitted into the screen frame, but this is a last resort, and is not to be recommended.

Now, our last section. When a screen must be made and no glass is at hand, it is a bad case, and it is impossible to make a really satisfactory substitute. But there is no need to give up in despair. Any translucent substance may be used; paper is often useful, the more transparent, but, at the same time, the more stiff the paper is, the better; or any fabric—a white handkerchief, for example, may be used. But whenever such a material is used, don't try and fit it in where the glass would fit, it is bound to wrinkle if you do. Either pin or stick it over the back of the frame, and make the necessary allowance for the difference in position after focussing is finished. The best way to fix either paper or fabric to the screen frame is to damp it slightly, and stick it round the edges with Scotch tape. It will then dry up tightly stretched.

But, after all, prevention is so obviously better than cure in the case of a broken screen, that a few hints may be useful. Never let your screen become loose in the frame; small wedges of cork or rubber will fix it securely. If anything goes wrong with the catches on the reversing back, it should be seen to at once. Always protect

your screen with a sheet of stout card when the camera is in its case, and when space permits, wrap your camera in the focussing cloth. A solid leather case is an expensive item in these days, but the added protection to the apparatus makes it a good investment.—A. G. WILLIS.

Photo-Mechanical Notes.

Printing on Wood for Engraving.

To those who are interested in the above process, the following formulæ may prove of service for obtaining photographs direct from the negative on to wood. It must be borne in mind that the negative must be made through a prism or with a mirror in order that when it is printed the image is laterally reversed.

In using the following formulæ it is advisable to brush the sides of the wood block with melted paraffin wax or with celluloid varnish, otherwise there is a danger of the wood warping through contact with water.

FORMULA I.

Make a 5 per cent. silver nitrate solution, also a saturated solution of potassium oxalate. Add the oxalate solution to the nitrate solution until precipitation is complete. Filter to obtain precipitate, which can be used at once or allowed to dry, taking care not to expose it to strong light. Next mix together equal quantities of a 5 per cent. gelatine solution, and a 10 per cent. solution of dextrine, and take a small quantity of this mixture together with a few grains of flake white and sufficient of the above precipitate to form a paste when rubbed on the wood with the finger. The paste should not be too thin. Finally brush the paste over the wood with a flat camel-hair brush to obtain an even coating, and allow it to dry in the dark. The amount of exposure required depends upon the negative and source of light. Using an enclosed arc lamp (6 amps. 200 volt) the exposure for a negative of average density at a distance of 15 inches from the light would be about 5 mins. After exposure, without preliminary washing, fix in a 10 per cent. solution of ammonia (.880), by holding face down for one minute, wash for one minute under a gentle stream of water, and put by to dry. It is advisable to keep the finished print from strong light until it is ready to work upon.

FORMULA II.

Prepare the following solutions:—

A.—Silver nitrate	15 grs.	1 gram.
Citric acid	15 grs.	1 gram.
Water (distilled).....	240 minims	15 c.c.s.
B.—Sodium chloride.....	3 grs.	0.2 gram.
Potassium bromide	6 grs.	0.4 gram.
Citric acid	15 grs.	1 gram.
Gelatine	10 grs.	0.7 gram.
Water (distilled).....	240 minims	15 c.c.s.

Mix the above solutions, filter and rub a sufficient quantity of the precipitate to form a smooth paste on the wood surface, brushing with a flat brush to obtain an even coating, afterwards allowing to dry in the dark. Should the precipitate be dry it may be worked into a paste by adding a few drops of a 5 per cent. solution of gelatine. The exposure with this formula is approximately the same as with Formula I. Fix in a 10 per cent. solution of ammonia (.880), holding face down for one minute, wash under a gentle stream of water, and allow to dry, when it is ready for the engraver.

FORMULA III.

In this formula use is made of the "blue printing" process with slight modifications. Make up the following solutions separately, then mix them and keep in a dark place.

A.—Ferric ammonia citrate (green crystals)	2 o s.	60 grams
Water	9 ozs.	250 c.c.s.
B.—Potassium ferricyanide	1½ ozs.	45 grams
Water	9 ozs.	250 c.c.s.

Pour a small quantity of gelatine and dextrine mixture, prepared as in Formula I, on the wood and add sufficient flake white to form a thin white paste. Coat the surface evenly by means of a flat brush, and when thoroughly dry flow over two or three times with the combined A and B solution. Expose until a faint image is visible.

With an enclosed arc lamp (6 amps. 200 volt) this will take about three minutes at 18 inches from the light for a negative of average density. Develop by dipping the block face down in a dish of clean cold water. The image may be brightened by immersing in a 1 per cent. solution of nitric acid. After allowing to dry naturally it is ready for use.

With each of the above formulæ it will be found that a contrasty negative will give the best result.

Use may also be made of the "Kodak Transferotype" paper, operations being carried out as indicated in the instructions found in the packet. In this case it should be remembered that the negative must be unreversed, i.e., not made through a prism or with a mirror. The chief objection to this process is that the gelatine is apt to split or chip when the engraver works upon it.—E. L. TURNER.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, July 21 to 26.

LENSES.—No. 18,463. Objectives for photographic, etc., purposes. L. B. Booth.

COMPLETE SPECIFICATIONS ACCEPTED,

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

HIGH TEMPERATURE DEVELOPMENT.—No. 128,337 (April 20, 1918).

—According to the invention, a hardening bath is provided for treating gelatine-surfaced photographic materials prior to subjecting them to the action of a developer, which bath contains formaline, paraformaldehyde, or a compound from which formaldehyde is readily generated, together with a salt (for example, sodium citrate or sodium sulphate or di-sodium ortho-phosphate) of the class which tends to raise the melting point of a gelatine jelly and to retard or restrict the swelling of dry gelatine in water.

The invention further consists in the process for developing gelatine-surfaced photographic materials at high temperatures consisting in first subjecting the material to a hardening bath such as above described, and then subjecting it to a developer. It is found that if a photographic plate, for example, be first hardened in the above manner, it can afterwards be developed or toned with ease by any of the known developers or toning baths at a high temperature.

The class of salts referred to includes acetates, tartrates, citrates, oxalates, sulphates, phosphates, chromates, bicarbonates and borates.

A formula for this preliminary bath may be as follows:—

40 per cent. formaline	¼ oz.
Sodium sulphate, crystals	2 oz.
or Di-sodium ortho-phosphate	1 oz.
Water, up to	10 oz.

or if paraformaldehyde be employed 50 grains of this may be used instead of the ¼ cz. of formaline.

The above formula may be compounded and kept indefinitely, or—

the paraformaldehyde and sodium sulphate or other salt in anhydrous form may be made up as powders or into pellets and sold in this condition for dissolving when required in the necessary quantity of water.

It has been found that by using this preliminary bath, photographic plates and other materials can be manipulated, that is developed, toned, fixed, washed or otherwise treated with aqueous solutions, at a temperature as high as 110 deg. F. without any cooling means being necessary. The salt retards the swelling and prevents melting of the gelatine while the formaline is penetrating and combining with it to form an insoluble film, so that even though the bath may be at as high a temperature as 110 deg. F. the gelatine has no opportunity to melt before it is hardened by the formaline.

The advantage of using the above ingredients as a preliminary bath to a developing bath is great as it disposes of the need of using a special developer. Further, the fact that no development is taking place during this hardening, enables the developing to be carried out afterwards without undue haste, whereas when the hardening material has been incorporated in the developer, the hardening action has scarcely begun before development is finished and this is so rapid that, as already stated, it cannot be controlled; moreover the hardening effect being imperfect, subsequent treatment, such as fixing and washing of the plate, is exceedingly difficult and at such temperatures as 100 deg. to 110 deg. F. it is impossible even to complete development itself before the gelatine melts. When, however, the hardening is effected in a preliminary bath as described, the developing and fixing and washing can all be subsequently carried out in practically the same manner and with almost as much ease as would be the case if operating in ordinary temperatures.

In practice it is usual to proceed with development immediately after rinsing off the excess of the preliminary hardening bath. Alexander Johnston Agnew, Frank Forster Renwick, both of Messrs. Ilford Limited, Ilford, Essex, and Ilford Limited, Ilford, Essex.

ENLARGING APPARATUS. No. 117,622 (July 4, 1917).—The base of the apparatus carries a hollow cone 2 which is light-tight and is closed at its rear by a dark slide 3 which carries the sensitive paper.

The end of the cone 2 may be of any usual construction to carry

a dark slide or a sheet of frosted glass, upon which the operator can see if the image is in the correct position.

4 is the lens of the apparatus. The two brackets 5 and 6 are completely separate from the cone 2 and are only connected by the base 1, and are each provided with a plano-convex lens so arranged as to form a condenser.

In front of the lens carried by the bracket 6 and also carried by this bracket is placed a plate of frosted glass 7 to diffuse the light from the lamp 8 which may be electric, incandescent gas, or acetylene.

The negative is placed on the plane face of the lens carried by the bracket 5 and is held in position by the plate of glass 9 supported by the springs which can be displaced sideways.

The presence of the diffusing glass 7 in front of the condenser is such that not only is the image reproduced well, but the distance between the light and the condenser need not be absolutely correct.—Pierre Boucard, Rue La Boetie, Paris, and Louis Lemaire, Rue de Haras, La Garenne-Colombes, Paris.

Spirit Sensitisers in Oil Printing.

SOME of the difficulties which the beginner in oil printing may experience must be put down (says M. J. McLaurin in the "Amateur Photographer" for August 6) to the use of methylated spirit in the sensitising bath. Commercial methylated spirit, I need hardly point out, is not a definite chemical compound; it is alcohol, to which impurities have been deliberately added to prevent its consumption as a beverage. Because what one worker buys as methylated spirit is suitable for the process, it by no means follows that what another gets is similarly suitable; and I have traced a whole series of failures to this cause.

There is no need to use the spirit sensitiser, although it must be admitted that it is a convenience, and, therefore, my advice would be that should the paper appear not to work well with the spirit, that this should be omitted altogether. If a night can be allowed to intervene between sensitising and printing, one of the baths in which the paper is immersed can be employed, but if instead of this a plain 5 per cent. solution of ammonium bichromate is used, applying it with a piece of flannel folded over a strip of glass, in exactly the same way as the spirit sensitiser is applied, it will be found that the paper will dry in an hour or two if it is hung up in a fairly roomy cupboard or in a darkened room.

My own impression is that such paper takes the pigment more "kindly" than when the spirit sensitiser is used, which is, on the face of it, likely, since most commercial methylated spirit is not completely volatile, but as it evaporates leaves some slight trace of greasiness behind it.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

CROYDON CAMERA CLUB.

Mr. H. Guy Johnson last week lectured on "Telephone Transmitters," sensitive instruments, and the recipients of more lurid language than anything under the sun. At first sight the subject selected might indeed seem to be depressing, for all know the feeling of despair in advance when the request for a number traverses the wires, and is calmly deliberated upon at the other end, regardless of the fact that the subscriber may be experiencing a gamut of human emotions other than the benign. Yet in Mr. Johnson's hands the subject was invested with real interest as he traced the history of transmitters from the earliest types. Enticed by the dry-humorist, Mr. F. C. Reynolds, he finally drew on the blackboard the connections and varied instruments for a complete transmitting wireless set, and as complexity grew on

complexity, so hilarity increased in proportion. Richly educative are these informal meetings.

The previous week the aforesaid humorist gave an admirable demonstration on "How to run the club lantern," with valuable hints on the deportment and duties of the lanternist, which frequently include a fine sprint after the departed lecturer, owing to the last slide being left in the carrier.

He also described lantern optics in a way all could understand, for the lecturer always acts on the exceedingly wise assumption that not a few of his audience have no knowledge whatever of the subject under consideration. With equal wisdom he made no attempt to expand unduly on the purely optical side, which abounds in traps for the intrepid.

A novel way of making effective digram slides was also shown by him. The lues are ruled and lettering, etc., made on lantern-size fine ground-glass with a 6 H pencil (not too finely pointed), and the ground-glass is then cemented with Canada balsam to a plain cover-glass, rendering the slide "all clear," bar, of course, the drawing. A quiet evening with the docile Canada balsam freely on tap should secure many diagram slides, together with other mementoes of the occasion.

A discussion of some elegance followed the demonstration, Mr. H. P. C. Harpur appropriately leading off. He spoke favourably of slides developed with pyro-ammonia, which, he said, notably improved in tone by prolonged baking in the lantern, provided they were not allowed to attain red-heat, which would be prejudicial. No explanation was offered, but doubtless the volatilisation of the ammonia accounts for the phenomenon; with the so-called "fixed alkalis" the case would be different. (The return of the hot weather seems to have affected our contributor.—Ed. "B.J.")

Commercial & Legal Intelligence.

LEGAL NOTICES.—The partnership between Charles Rowe Major, Charles Howard Major, and Cyril Lawson Major, carrying on business as photographers at 152, Union Street, Plymouth, and Courtenay Street, Newton Abbot, both in Devon, under the style of C. R. Major and Sons, has been dissolved by mutual consent as from May 17 last. All debts due to and owing by the late firm will be received and paid by C. R. Major and C. L. Major, under the style of C. R. Major and Son.

A first and final dividend of 20s. in the £, and 4 per cent. interest, has been declared in the estate of William Curtis, photographic postcard maker and publisher, Kilnsey, near Skipton, Yorkshire. This dividend is obtainable at the Official Receiver's Office, 12, Duke Street, Bradford.

NEW COMPANIES.

PORTRAITURE, LTD.—This private company was registered on July 24, with a capital of £10,000, in £1 shares (5,000 15 per cent. cumulative preference). Objects: To carry on the business of photographers, portrait and miniature painters, frame makers, etc. An agreement with Elwin Neame, Ltd., is contemplated. The subscribers (each with one share) are:—S. Elwin Neame, 11, Rotherwick Road, Golders Green, N.W.4, photographer; W. A. E. Neame, Allestree, The Drive, Sidcup, Kent, bank accountant. The first directors are S. Elwin Neame and Wilfred Yonge, 7, Chatsworth Road, West Norwood, S.E. S. Elwin Neame is manager for life. Registered office: Onslow Place, South Kensington, S.W.

FORTHCOMING EXHIBITIONS.

September 13 to October 11.—London Salon of Photography. Entries close September 2. Hon. sec., 5a, Pall Mall East, London, S.W.1.

MAJOR F. C. V. LAWS, executive head of the Photographic Section of the R.A.F., appears in the list of those who have received permanent commissions in the Royal Air Force. In the case of many officers who are now taking a permanent commission, a lowering of rank by one step is not an infrequent feature of the present readjustment from a war to a peace basis. Since, however, Major Laws retains his full rank, it may be conjectured that he will remain at the head of the Photographic Section, with which he has been intimately associated since the outbreak of war.

Correspondence.

. Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

DISHES FOR HYPO-ALUM TONING.

To the Editors.

Gentlemen,—Regarding your note at the foot of letter from the Research Laboratory, Eastman Kodak Co. We have made quite a large number of hypo-alum toning baths for Messrs. Illingworth and Co., and have also supplied them to other houses, and find they have always given satisfaction. These baths are made in sheet steel enamelled. We should also like to point out that it is not possible to make dishes in pure tin, as pure tin is not obtainable in the sheet.—Yours faithfully,

DAVID ALLAN.

Whitfield Works, 107, Mansfield Street, p.p. J. HAZELL.
Kingsland Road, London, E.2, August 2, 1919.

CO-OPERATIVE HOLIDAY CLOSING OF STUDIOS.

To the Editors.

Gentlemen,—May I be permitted, on behalf of the Council (now in recess), to congratulate Northampton photographers, and Mr. Greenway in particular, on the success they are achieving in this matter of combined closing for holiday purposes.

The Council would very much like to see all photographers come together for "district" purposes, which, as a rule, can be arranged much better locally than from an outside centre.

Mr. Greenway adds: "Are the P.P.A. Council alive to their responsibilities of sagacious leadership?" I can only say, in reply, that if he will offer any suggestions, I shall be only too glad of the opportunity to bring them before the Council, and keep him informed as to the results. I am sure I am correct in saying that the Council wants and welcomes all the help and support from its members that it is possible to secure.—Sincerely yours,

S. H. FRY, Hon. Sec.

5, Highbury Grove, London, N.5, August 2, 1919.

AN ASSISTANTS' PROFESSIONAL PHOTOGRAPHIC ASSOCIATION.

To the Editors.

Gentlemen,—"Experience," in his letter this week, raises a point I had not in mind when I wrote suggesting local effort in forming a photographic assistants' association. I also fail to see how such an association would benefit by the patronage of the Master Photographers' Association. It must stand by its own efforts. These efforts up to now have been very feeble, and my letter has brought me two in return. If there are only three of us in Lancashire interested, and each in a different town, I am afraid "Experience" will wait a long time for his fencing tournament.

Personally, I do not see anything particularly arrogant in the title of the Master Photographers' Association, and I fail to see why any society should not be at liberty to choose its own title. The particular member of this association who employs "Experience" must have some good points which counteract his arrogance, or he would not be able to keep any assistant of spirit for a period of eight years.—Yours faithfully,

WM. ASPDEN.

165, Church Road, Smithells, Bolton, August 1, 1919.

HOW'S THIS FOR PROFITEERING?

To the Editors.

Gentlemen,—I have just given up professional photography, and in clearing up generally I found I had a number of boards quite good and serviceable that had been sent to me by various enlarging houses that had at different times done work for me, fourteen in all to be exact, and for which I had been charged anything from 2s. per board upwards. I sent these to a firm which works for the trade, and this is the reply:—"By allowance 1s. 6d. I am allowing this in order to fully cover cost of carriage. The wood, however, is of little use to me, the only board that was

mine being too badly broken to use." Now, as I had written to this gentleman asking him if these boards were of use, and as I had his reply he would "redit value, I sent same on carriage paid. The fourteen boards could be used in the business, and would, I daresay, be charged at this gentleman's usual rates, namely, 2s. per board or more, and he would thus be getting 28s. for what he was paying 1s. 6d. for. I wrote per return asking the good man to return the boards carriage forward, as I did not like taking so much money at one time.—Yours faithfully,

THANKFUL-OUT-OF-IT.

July 30, 1919.

FLATTENING POSTCARDS.

To the Editors.

Gentlemen,—I read with interest the article in the "B.J." of July 25 by Mr. M. C. Milburn on the flattening of postcards and his method for the prevention of curling. He remarks that placing cards under pressure is uncertain and unsatisfactory, and that he has seen a batch of cards so firmly stuck together that they were as solid as a block of wood. Such a result, it seems to me, can only be possible from lack of just enough common sense to know when the cards are sufficiently dry not to stick together.

Pressure has been the method I have always used, and of the many thousands so treated I do not remember a single case of trouble.

In the earlier days I simply used heavy weights, and although this answered the purpose quite well, it occurred to me that something

more convenient would be more useful. I enclose photograph of a press I made years ago, and which has given perfect satisfaction. I think the picture shows what a simple affair it is, and should, without any explanation, enable anyone to make a similar machine should he so wish. It may help if I mention the component parts.

The weight.—A box filled with old negatives (mine weighs about 30 lbs.).

Runners for Weight.—A couple of stair rods, cut to size as required.

Lever.—Mine is a hammer handle let in a square piece of wood, but, of course, can be made in any other way.

Posts and Cross Bar.—About 1½-in. quartering.

Spring.—One off an old printing frame bent suitably to work against a piece of wood cut with a notch to hold the weight while placing cards below. This is screwed to one of the posts, and must work freely.

Board or Platform.—1 in. in thickness, about 8 ins. in width, length according to size of machine.

Keep a couple of dozen old negatives on the platform below the weight. Place cards in dozens between plates, let them remain three

or four hours under weight, and results will be perfect. Anyway, that has been my experience.

By Mr. Milburn's method one has to manipulate each card singly, whereas with the above you can deal in dozens, and leave them to take care of themselves.—Yours truly,

J. STANLEY.

Dulwich House Studio, Hamlet Court Road, Westcliffe-on-Sea.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed (or reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

C. M.—With the additional glass you will be able to work well on both sides, but you did not show this on your plan. Sage green is a very good colour for the walls, but it should not be too light.

C. C.—We do not know the name "Besus" as applying to lenses. From the brief particulars you give it is impossible to say what the value is. Apparently it is a fairly modern wide-angle, but not at all a suitable lens for portraiture.

C. W.—There is no necessity to include the makers' or publishers' name on the view postcards. Most photographers who publish such cards prefer to put their name on them as an advertisement. No permission is required for taking photographs of streets in ordinary circumstances. It is, of course, different in the case of processions and public functions, where, in most large towns, police permission is required for photography.

J. W.—There is no method of removing the reflections from the negatives. Evidently yours was a difficult subject, and we suppose it was impossible to get a good lighting of the shop while buildings on the opposite side of the road were not equally strongly lighted. Under such conditions about the best alternative is to arrange for the shop front to be photographed by night by flashlight, which, unless it is a very narrow thoroughfare, will leave the buildings on the other side unilluminated.

E. D. M.—The formula commonly attributed to the green ferric ammonium citrate is that first given by Valenta in a paper in "Photographische Korrespondenz," 1897, p. 77. We are sorry we cannot give you references to a translation of this paper, which apparently was not reprinted in the "B.J." at the time. Probably the nearest place where you can see a file of "Photographische Korrespondenz" is in the photographic and printing faculty of the Manchester College of Technology.

A. E.—As you do not give the aspect of your studio it is difficult to say what blinds you require. Your best plan would be to fit a set of festoon blinds as recommended in "The Portrait Studio," which our publishers will send you for 10d., post free. These blinds, if made of easement cloth, would not cost much, and you would have full control of the light. The print sent shows very fair lighting, but it was taken so late in that day that it proves nothing, the light by that time being naturally subdued.

W. N.—The tin protochloride is used more as a preparation for making the silver take to the glass than as a cleaning agent. As an alternative cleaner there is nothing better than strong nitric acid mixed with about equal bulk of water, but you can obtain the

stannous chloride quite easily from any dealers in chemicals, such as Messrs. Johnson and Sons, 23, Cross Street, Finsbury, London, E.C. It is a slow business making it by dissolving pure tin in hydrochloric acid. One requires to keep the strongly fuming acid at a boiling temperature for two or three hours.

W. B.—There is no reliable method of getting heliotrope or violet tones on any paper, but about the best process is to print on matt collodion P.O.P., to print deeply, and to tone in the following bath:—

Hydrochloric acid	6 ozs.
Gold chloride	10 grs.
Water to make	20 ozs.,

afterwards fixing in 5 per cent. hypo. A larger proportion of acid gives prints tending still more to violet.

S. W.—Four 1,000 c.p. lamps should answer your requirements. These should each be fitted with a white reflector and thin calico diffuser. We should fit them on the side nearest the high wall, in a curve, the first being nearly opposite the centre of the background eight feet away and about eight feet from the floor, the next a foot nearer the background and seven feet from the floor, the other two will serve as a side light and may be still lower. You will, of course, require a reflector on the shadow side of the sitter. A small, round head screen covered with cheese cloth is very useful for local control of the lighting.

D. C. S.—1. If you are working with a box printer there is no difficulty in having an attachment made so that the negative (and the thin paper mask laid upon it) are held down beneath a frame of just the size to take the postcard, the pressure back of the printer being fitted with a special piece to press the postcard within the frame. You could easily make a fitment of this kind yourself or get it from one of the makers of printing boxes, such as Houghtons or Marions. 2. None of the chemicals mentioned in the formulæ require storing in non-actinic bottles (we suppose you mean non-actinic, although you say actinic), nor are the solutions any better for being kept in orange or dark brown bottles.

P. J.—For good lighting and rapid exposures a flash cabinet of the kind described in the "B.J." of December 6 last is immensely superior to any gas installation, but the question for you is whether you can instal a proper shaft and ventilation for carrying off the magnesium smoke. If you can, our advice is greatly in favour of the flash cabinet, although photographers in this country make very little use of it, whereas in America and France you find it used by a large number of photographers. One consideration against the gas installation is the comparatively small size and low height of your room. If the gas is going continuously for any length of time the place will get very hot, we should say unbearably so, in hot weather.

H. J.—1. We have no idea what can cause blue stain in the use of persulphate. A negative after persulphate reduction is very sensitive to stain from outside contamination, and apparently some chemical must have reached it by contamination from the fingers. 2. Both metol and hydroquinone may be discoloured and still work well, but there is no means of knowing whether this is so or not except by making up a bath of developer and trying it. 3. A very thin coat of backing will do in the case of ordinary subjects, but if there is liability to extra halation, you want a fairly substantial coating. If the backing is a mixture of caramel and pigment, the coating should be so thick that you could not read your own writing through it if you laid a plain piece of glass with the coating on it down on to the paper.

W. A. S.—Evidently your negative is not sufficiently strong, that is contrasty, for the printing paper. That is one cause of the degraded sky, and another probably is that the developer gradually got exhausted and you kept prints too long in it with the object of bringing them up to sufficient vigour. Your remedy for thin skies in your negatives is longer development or, alternatively, more of the stock solution of pyro and alkali in a given bulk of the tank developer. You can improve existing negatives by intensification, say, with chromium intensifier, but if you give reasonable exposure and develop long enough you should have no difficulty in getting ample density in the sky without needing to intensify. 2. Unless you can find somebody in your district to give you a few lessons the only thing for you to do is to take a week or two's

course at the day classes of the Photographic School of the Regent Street Polytechnic, London, W.

B. B.—One is apt at the first trial to use too much of the wax medium, and that is probably one of the causes of its not drying quickly. Other causes are adulterants of tallow in the wax and paraffin in the turpentine. Roughly speaking, tested on glass the medium should dry in a few minutes, that is, as soon as the solvent has evaporated it should revert to its former hard state. In practice all one wants is to reduce the wax to a solution to enable one to pass the colour over the portion in hand, and before it finally sets to smooth it to one's liking. Only the merest film of wax is required to hold the tint to paper. Wax medium is easily and cheaply made to your liking, and can be quick or slow drying according to the solvent used, hard drying by the addition of gum elemi or Canada balsam. Soap is added merely as an emulsifier, and can be dispensed with. If a very thin film of wax is spread on paper, dry powder colour, pastel or charcoal applied and then steamed, it will be found to hold the colour sufficiently. Such methods give a double value to pastel.

H. N.—Evidently the enlargements are splattered with some brown staining substance on the mounts as well as on the prints. Looked at through a magnifier the stains look exactly the same on both mount and print, and in that fact we think that you should have the strongest defence against any claims which are being made, for it is incredible that you would send out mounts stained in this way and equally incredible that your customer would accept them. From what you say, it appears to be suggested that the stains were not visible when the prints were received, but developed in some way on the photographs. While that would be conceivable in the case of the prints, it is inconceivable in the case of the mounts. We cannot venture an opinion as to the cause of the spots and markings. They have not the appearance of any which could arise from defective paper or from defects in making the prints. From the strong colour and density of the spots they certainly have the appearance of having been caused by tiny splashes of liquid. Possibly splashes of permanganate would give rise to brown spots of this kind on both mount and print, but if, as we think, the spots are due to some liquid splashed on, there are, of course, hosts of substances which might have produced them.

Line Advertisements.

Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.

(No reduction for a series.)

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed Adv'ts should reach the Publishers on Monday morning.
The insertion of an Advertisement in any definite issue cannot be guaranteed.

SUMMARY.

A contributed article gives working instructions in the making of multiple vignettted prints on print-out papers by a method which can be readily carried out by those without special skill in such work. (P. 468.)

A new feature—viz., topical notes on Press Photography—will be found on page 475. We may make it a regular one if sufficient support is forthcoming.

The astonishing suggestion is reported to have been made at an R.A.F. Photo-section dinner that "every town, river, railway, and road in the country" should be photographed from the air. (P. 478.)

If photographers cannot be persuaded to adopt colour-sensitive plates and a light-filter for sun-tanned, then at least the precaution should be taken to let exposure be on a very liberal scale. We refer to this question in a leading article on page 466.

A valuable new aid to the practice of orthochromatic photography is provided by the "photographic-vision" filters now being introduced by the Ilford Co. (P. 474.)

Methods for the making of enlarged negatives are the subject of some "comparative notes," in which the advantages and drawbacks of the various conjunctions of processes are passed in review. Those dealt with this week are on the enlarged-transparency system. (P. 467.)

The heat-wave presumably has made the article by "Practicus" of exceptional brevity. Its topic is the element of personality in the ordinary affairs of a studio. (P. 470.)

A paper by Drs. A. W. Porter and R. E. Slade reviews and revises certain incomplete studies of Hurter and Driffield in the theory of photographic printing. (P. 471.)

Time-saving hints on the making of copies form the subject of "Assistants' Notes." (P. 474.)

In the design of field cameras for professional use greater importance might well be laid upon rigidity of the lens-front if it is a question of sacrificing this feature to portability. (P. 466.)

The question of varying time or distance in the making of prints by artificial light is the subject of a practical paragraph on page 466.

The prospectus of the Royal Photographic Society's Exhibition is published, and announces September 20 as the latest day for the receipt of entries. (P. 465.)

EX-CATHEDRA.

The R.P.S. Exhibition. The prospectus of the forthcoming sixty-fourth exhibition of the Royal Photographic Society is, for some reason, very late in appearance, but is now obtainable on application to the Secretary, 35, Russell Square, London, W.C.1. It discloses the fact that in the pictorial section this year the society is planning a lighter and more pleasant appearance of the walls as a whole by stipulating, as has already been done from "another place," that exhibits be sent unframed, and that white or light-tinted mounts of one or other of the sizes, 16 by 12, 20 by 16, and 22 by 18 ins. be used. Passepartouts of these sizes and tints of mount may, however, be sent. The latest days for the receipt of exhibits are September 19 by carrier and September 20 by hand, the exhibition opening on October 13. In the pictorial section the selecting and judging committee consists of Messrs. Bertram Cox, J. Dudley Johnston, and Alex Keighley. Messrs. F. T. Hollyer and W. L. F. Wastell select and judge pictorial colour transparencies, whilst those of technical or scientific interest will be judged by the committee in the general scientific section, consisting of Messrs. G. Ardaseer, Charles R. Davidson, Hugh Main, and Drs. Robert Knox and Geo. H. Rodman. Medals will be placed at the disposal of judges in the colour and technical sections, but not in that for pictorial work.

* * *

Reducing Contrast. It is generally believed that the per-sulphate reducer does not attack the thinner portions of a negative, confining its action to the high-lights only, but this is not altogether true. If this were so it would be possible to leave the image in the solution indefinitely, which we know is not the case. Therefore, it is well to remember that we have in the chromium intensifier a very useful means of improving negatives which have a considerable amount of thin shadow-detail together with dense high-lights which quite preclude the possibility of getting a really good print both in gradation and colour by any process. Any attempt at reduction will still further weaken the thinner parts, very much if the ferricyanide and hypo method is used, and less if persulphate be employed; with the latter, however, the high-lights are reduced in so much greater a proportion that they are printable before the shadow-detail is hopelessly buried, and a much more harmonious result can be obtained. If we adopt the chromium method we can not only reduce the high-lights but intensify the shadow parts, so that the finished negative will closely approximate to one which has received full exposure and correct development. The procedure is exactly the same as for intensification, with one exception, that the re-development with amidol is not completed but arrested at any desired stage by rinsing and transferring to a normal

fixing bath, which dissolves that portion of the dense image which has not been reconverted to the metallic state. Uneven development must be guarded against, and we have found it useful to blot off the surface moisture from the bleached image so that the developer commences its action evenly all over.

* * *

The Weight of the Lens. The tendency for some years past on the part of all camera makers has been to reduce weight and bulk as much as possible among all classes of apparatus, and even the field camera has been not unaffected by the general trend. There seems in our opinion in many patterns a decided want of rigidity in the front of these instruments that was not in evidence on apparatus made a score of years ago. The lightly constructed front is all very well if only the light modern anastigmats are to be employed, but if an older pattern of rapid symmetrical originally made to cover a much larger plate is fitted, the increased weight of such a lens tends to a decided loss of rigidity. It may even be that the camera front itself, if the instrument is of the tapering bellows pattern, is not large enough to accommodate such a large lens. In field-camera construction there is much to be said for the square-bellows pattern on the score of rigidity in that it will allow almost any make and weight of lens to be fitted without strain or lack of rigidity of the front during exposure; also there is no risk of cut-off when a lens of short focus is employed. We have no wish to decry the modern field camera, but this is one of those cases where improvement in one respect is made at the expense of lessened efficiency in others.

* * *

When a V.P. Scored. Yet another instance of the practical value of the vest-pocket camera came under our notice recently. A photographer was called in to take a group round the table at a children's tea party. The circumstances were against the production of a good result. The little sitters were of all ages and more or less restless. The group was in different planes, necessitating careful focussing and stopping down, and the light was bad. Two or three exposures were made with an ordinary field camera, and then almost in desperation the photographer ran off half a dozen rapid exposures upon a spool of film in quite an ordinary vest-pocket camera. When the whole of the exposures were developed, comparison proved almost an astonishing revelation. Each of the tiny negatives was in every practical point perfect, while those with the larger instrument showed that several of the little sitters had moved during the long exposure. From the selected negative several dozen prints were made through the enlarger which delighted the customer and enhanced the reputation of the photographer.

* * *

Time or Distance. There are, as every photographer knows, two ways of varying the exposure when printing upon bromide or similar papers. One is to give a longer or shorter time at a fixed distance, and the other is to vary the distance while the length of exposure remains the same. A combination of both ways is sometimes found necessary. At first sight it may appear that the same result would be arrived at by either method, provided that an exactly equivalent exposure were given, and this is perhaps true within certain limits of density in the negatives. But when abnormally thin or thick images have to be dealt with it will be found that the results obtained differ greatly in the matter of contrast. For such negatives variation of distance will be found to give not only the best gradation in the print, but in the case of very thin images of uniformity in depth and colour.

Supposing that our exposure to a given lamp at a distance of one foot is eight seconds for a normal negative, and that we wish to print from a negative which requires only one-fourth of this time, we shall find that there is a great difference between two prints, one of which has received two seconds at one foot and the other eight seconds at two feet, while a still further difference will be found if the distance be increased to eight feet and the exposure to 128 seconds. Conversely with dense negatives the distance must be reduced, or if this becomes too short to secure even illumination of the negative a stronger light must be used. In all cases the exposure should be regulated so that the image is thoroughly developed, for by this only can good colour be obtained. Where a fixed distance only is available, as in printing boxes, the light must be reduced by the interposition of one or more sheets of thin paper, so that an exposure of sufficient duration can be given.

HOLIDAY COMPLEXIONS.

At this time of year the portrait photographer finds himself faced with the difficulty of having many sitters whose complexions would do credit to some of the lighter Indian races, yet who expect that their portraits will be those of ordinary white folk. It is said that in America those portraitists who have negroes or mulattos in their *clientèle* succeed in business according to the degree of whiteness of skin which they can confer upon their sitters, and the same thing holds good with holiday-makers here.

We do not think we are wrong in asserting that the majority of portrait negatives, taken under normal conditions, are under-exposed. In some cases this is done designedly to produce certain broad effects, but generally it is done without its being realised. If we look at any collection of portraits of sitters in dark clothing we find that there is little detail in anything except the face and hands, the drapery being very faintly defined. Now if this be so with a pale-faced sitter, what must it be when a bronzed complexion has to be dealt with? Fortunately, this problem presents itself at a time of year when the light is good and full exposures given without risk of movement. Three or even four times the exposure usually given will not be too much for extreme cases, and there need be no fear that light draperies will suffer in consequence; in fact, they will be improved in rendering because they will not be made too dense in the endeavour to bring the face up to printing density. Those who have done much copying realise the great increase in exposure necessary when working from an original upon toned paper, and the sunburnt sitter is rather more than "toned." The lighting, too, calls for some modification. More light can be admitted, and the reflector used freely without fear of flatness, and it will be found that the larger the aperture of the lens the more harmonious will be the result. From the scientific point of view it is correct to say that given the ordinary system of diaphragm apertures each step downwards from the full opening requires double the exposure that the preceding one did, but it does not hold good in practice with all classes of subject. If anyone doubts it, let him try two plates on a bronze figure or other article, one at $f/4$ and the other at $f/32$, giving the theoretical increase in exposure for the latter and develop both in the same dish for the same time. In colour photography, either by the screen-plate or trichrome process, much of the colour value is lost if a small aperture is used, and the same is true, to a smaller extent, in ordinary work.

It is, we fear, like ploughing the sand to suggest that rapid orthochromatic plates are preferable to ordinary

ones for all classes of portraiture. There are no difficulties or disadvantages connected with their use, and even without a screen they are helpful with any subject having a yellow or brownish tinge. Panchromatic plates we hardly dare mention, as they must be manipulated in total darkness, and it takes much persuasion to get most operators to believe that a good negative can be made without watching it through the development. Those who are free from this superstition will find that the latest introduction in panchromatics, the new Ilford plate of this type, possess remarkable powers of colour-rendering in an unscreened condition, while a light screen gives still better results. It is in colour-sensitiveness of the emulsion that the photographer of dusky complexions will find his most effective weapon, but if such means cannot be reconciled with his antipathies, the next best maxim for him is ample exposure of his ordinary colour-blind plate.

COMPARATIVE NOTES ON METHODS OF MAKING ENLARGED NEGATIVES.

I.

In these days of development papers and of the facility of enlarging, the making of enlarged negatives has naturally fallen into a lesser degree of importance to the professional photographer and perhaps interests chiefly the more serious type of amateur desirous of producing from his small negatives large prints in the oil and other processes which require an enlarged negative for daylight printing. Even professionals who do their own printing in carbon or platinum are apt to shirk the making of the enlarged negative when a carbon or platinum enlargement is called for, and to pass on such work to a trade house. Nevertheless, the variety of means by which an enlarged negative may be made is sufficiently great to offer a particular choice appropriate to the conveniences in the way of apparatus, etc., which are available or to the purpose for which the enlarged negative is required. Since in our experience both professional and amateur workers are oftentimes in doubt as to the relative merits of these means, it may be of service to many if we pass them briefly in review, not with the intention of offering working instructions, but with the object of indicating the advisable procedure in given circumstances. The making of enlarged negatives cannot be called a "process," since it consists simply in the conjunction or combination of processes which, for other purposes, are familiar to every photographer. The particular manner in which these processes are employed in conjunction appears to be a subject on which something may very usefully be said, and the present notes are intended to be read in that sense.

Generally speaking, the making of enlarged negatives follows one or other of two systems: (1) the making of a positive transparency the same size as the negative and its enlargement to produce the enlarged negative, and (2) the production of an enlarged transparency of the size which the enlarged negative is required to be and the making of the latter from this either by contact or, more usually, in the camera. From a consideration of the different materials which are available for the making of the intermediate transparency and the enlarged negative it will be seen that some dozen or so different methods may be followed. In order to provide a preliminary swift glance over these different methods we borrow from a past issue of the "Photo-Miniature" a shorthand representation of them devised by labelling as P1, P2, etc., the methods for making the positive transparency, and as N1, N2, etc., the methods for producing the enlarged negative from it. Thus, adopting this notation, we can bring within a very

small space an outline of the methods and materials which are available.

PROCESSES FOR POSITIVE TRANSPARENCY.

Same size as original negative.	Same size as enlarged negative.
P1, dry-plate, or	P4, dry-plate
P2, carbon tissue, or	or Transferotype or
P3, print-out paper.	development paper.

PROCESSES FOR ENLARGED NEGATIVE.

From positive same size as original negative.	From positive same size as enlarged negative.
N1, dry-plate or film, or	N3, dry-plate or film, or
N2, bromide or Transferotype paper.	N4, bromide or Transferotype paper, or
	N4, carbon tissue.

COMPLETE PROCESSES.

No.	Positive.	Negative.
1.	P1, dry-plate.	N1, dry-plate or film.
2.	P2, carbon tissue.	N1, dry-plate or film.
3.	P1, dry-plate.	N2, bromide or Transferotype paper.
4.	P3, print-out paper.	N1, dry-plate or film.
5.	P3, print-out paper.	N2, bromide or Transferotype paper.
6.	P4, dry-plate or development or Transferotype paper.	N3, dry-plate or film.
7.	P4, dry-plate, development or Transferotype paper.	N4, bromide paper, Transferotype paper.
8.	P4, dry-plate, development or Transferotype paper.	N5, carbon tissue.

Perhaps the first question which arises from a study of the above table is whether choice should be made of a method of working from a small transparency or from one of the full-size of the enlarged negative. What is gained by the expenditure of two large plates as against one, and are there any disadvantages attached to the former system? The enlarged-transparency method is beyond question the most perfect process of making an enlarged negative where one requires the opportunity of carrying out improvements by working up or by rubbing down, or, indeed, by any form of retouching. On this account it is the method greatly favoured by leading pictorial photographers whose work is done in platinotype or in carbon. We have the recollection of Mr. W. R. Bland having confessed somewhere that one article in these pages years ago, commending this form of the enlarging process, had in itself amply repaid him for a twenty years' subscription to the Journal. Moreover, apart from this question of retouching in one shape or another, the enlarged-transparency method offers a facility and precision in the insertion of clouds or skies into the enlarged negative which is not yielded by the system of working from a small transparency. Against these advantages must be set the necessity, if plates are used, for a camera taking a plate the size of the enlarged negative and also for proper means of illuminating the enlarged transparency. If dry-plates were of such perfect flatness that a 12 x 10 negative could be printed by contact from a 12 x 10 transparency, these requirements would obviously disappear, but in the use of ordinary dry-plates it is necessary that the transparency should be copied same size in the camera in order to secure satisfactory definition throughout all parts of the image: also there are those who are ready to maintain that a higher quality of enlarged negatives is produced in this way. The disability of the enlarged-transparency system in this respect has been removed to some extent by the introduction of the Eastman Portrait film, which, for moderate sizes, may be used as the sensitive material for the enlarged negative, and can be printed quite satisfactorily by contact in a frame of the solid build such as is used for carbon printing. Similarly, an alternative to the use of transparent portrait film is bromide paper, Trans-

ferotype paper or carbon tissue, as represented by processes 7 and 8. The use of bromide or Transferotype paper reduces cost considerably, while on the other hand it does so at some sacrifice of quality, and, moreover, is much less convenient for the addition of clouds or skies. The slowness of printing, in the case of bromide, is a further disadvantage, whilst the slight grain of either bromide or Transferotype paper limits the employment of the enlarged negative to papers having a matt or rougher surface. Probably for a very large proportion of the uses to which enlarged negatives are put by the pictorially inclined worker, this latter is by no means a drawback. With

these qualifications it may be said that the enlarged-transparency system recommends itself to those who, working chiefly for pictorial ends, have at their disposal a large copying camera and the means, preferably a window looking upon a clear sky, for the illumination of the transparency.

The merits of the system according to which a small transparency is enlarged are almost too obvious to need pointing out: the more debatable considerations arise in selecting the material for the enlargement of the small transparency and also for the making of the transparency itself. These must be deferred to a succeeding article.

MULTIPLE VIGNETTES WITH PRINT-OUT PAPERS.

In the case of bromide and gaslight papers multiple vignettes present little difficulty with register lines on the back of the paper, which, in one well-known method, is caused to travel and a fresh surface exposed for every negative, in turn. In the absence of some special contrivance, this is not possible with daylight printing papers, and if one were devised it is doubtful whether it would present any advantage. It therefore follows that it is compulsory to use a printing frame large enough to take the strip of paper, and in the majority of cases it is also obligatory that two successive printings be employed, for the reason that in the print the distances required between the vignетted heads is usually less than the distances between the same points when the negatives are laid side by side in contact. Consequently, they cannot be printed simultaneously unless the negatives are cut down, which, for various reasons, is often not desirable. In the method to be described this is presumed to be so, and although it originated with the writer, there is no doubt it has frequently been evolved, being a plan more or less forced on one by the conditions, though details of procedure may vary.

The idea was to so scheme out things that the general set-up might be handed to any intelligent young lady printer, who, after familiarising herself with the hang of the thing, should experience no difficulty in printing the multiple vignettes, and it was found successful in practice. Feminine nature is stated to be complex, and this may be so, but assuredly it does not respond sympathetically to undue complexities in printing.

The Guide Print.

A piece of white paper is first cut the size of the printing paper to be employed. Rough proofs (preferably fixed) from the negatives are trimmed close to the subject and stuck down in correct position on the paper. With standing figures vertical lines cutting them truly can be made on the proofs, and a set-square applied to them, and the bottom of the paper will ensure the figures standing upright.

The position, spacing, etc., will depend on the subjects and the taste of the printer, but often the chins are placed equidistant from the bottom of the paper. Before the prints are stuck down, horizontal lines are ruled across them, roughly at right-angles to the vertical, and cutting the extremities of the chins: a horizontal line ruled across the paper at the right distance from the bottom will ensure this. It is quite necessary to have the guide print correct, as it is the basis for the subsequent setting-up. Finally, the proofs are given consecutive numbers, numbering from left to right in the customary way, and the negatives are plainly marked to correspond.

Outline of Procedure.

In the following notes a triple vignette is taken as an example, but exactly the same principle applies to any number

of negatives. Briefly, it consists in assembling them in a cardboard carrier behind a multiple immovable vignette, with openings appropriate to the negatives to be printed underneath. It is therefore necessary that they occupy the correct position in the printing frame relative to each other and their corresponding opening in the vignette. With a triple vignette the centre negative is, say, printed first with the openings in the carrier on either side masked out to prevent any possible action by stray light. The remaining two negatives are then printed together with the space between them masked out. In both cases the openings not in use in the vignette are covered. Accordingly, we have to make a card carrier, the vignette, and two masks, and devise some simple scheme for registration.

Procedure.

A piece of white tissue paper is taken larger than the guide print, is placed over it, and the outlines of the subjects are boldly traced, taking care no shift occurs whilst doing so. Mark also by lines or dots the position of the bottom and sides of the guide print. Remove the tissue paper, turn it over, and repeat all lines on the side now uppermost. Consecutively number the subjects from *right to left*, and mark the paper "film side."

At the bottom of every negative make a mark (for registration) on the film of the rebate. Place the negatives in turn, film uppermost, on the tissue paper so that the image corresponds with the lines drawn, and with a pencil draw round the edges of the glass, and also place a dot against the registering mark. If the negatives are dense, this may have to be done by transmitted light.

The diagram illustrates affairs so far as we have now got. The position of the negatives is shown at 1, 2, and 3 (indicating

their position in the card-carrier subsequently to be cut out). The bottom of the printing paper is indicated at *a*, *a'*; the sides at *b*, *b'*. The registering marks *c* are not in all cases necessary, but they insure exactitude, and are no trouble to include.

The Masks.

It will be apparent from the diagram that when the middle negative is being printed a space will be left on each side through which light may creep from the central vignette—edges of negatives have a nice trick of catching stray light and distributing it where it is most decidedly not wanted. These spaces, therefore, require protection, together with the clear rebate of the negative being printed.

The mask is made by laying down another piece of tissue paper of the requisite size on the diagram and tracing round inside the central rectangle; about $\frac{1}{4}$ in. clearance will more than allow for the rebate. The paper just drawn upon is turned over, a dab of gum is placed within the rectangle, and the tissue paper is stuck down on orange paper and the rectangle cut out. In the same way, a second mask is made to shield the central space when negatives 1 and 3 are being printed, and also protecting their rebates. The masks should not extend so as to cover the lines indicating the bottom and sides of the printing paper.

The Multiple Vignettes.

Again, we lay another piece of tissue paper on the diagram (or on the guide print if the images show through the tissue), and the amount of each subject is traced, taking care no shift occurs. The tissue paper is stuck down on brown paper or thin card in the same way as mentioned for the masks, and enables the three vignette openings to be cut out in exactly the right position relative to each other. Mark the side on which the tissue was stuck "under-side."

The Card Carrier.

We now take the diagram and on the reverse side put dabs of gum well distributed over the inside of the three rectangles, and stick it down on card. Prick through *a*, *a'*, and *b*, *b'*, and also the registering dots *c*. The boundaries of 1, 2 and 3 are then cut out and the lines representing the bottom and sides of the printing paper are reproduced with a pencil. A touch of the pencil to the pricked dots *c* will make them plainer.

Assembling.

The card carrier is inserted in the printing frame, and, if not an exact fit, is attached to the glass by gummed strips. Negatives 1 and 3 are placed in their respective openings in the carrier. If a reasonable fit, well and good; if not, the registering marks on the negatives and dots on the carrier will ensure exact positions, and applied gummed slips temporarily retain them.

FORTHCOMING EXHIBITIONS.

September 13 to October 11.—London Salon of Photography. Entries close September 2. Hon. sec., 5a, Pall Mall East, London, S.W.1.

SHEFFIELD AND DISTRICT PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.—A meeting was held on Wednesday, July 30, and by the kindness of Miss E. M. Eadon her fine studio and workrooms were placed at the disposal of the Association for the purpose of a demonstration of "tank development," given by Mr. J. H. Lawrence, of the Kodak Co. Plates and flat films were exposed in the studio and then developed in tanks. Mr. Lawrence gave a very interesting lecture on tank development while development was proceeding, and explained that "whatever the exposure—within reason, of course—a negative would be got by tank development that would have the right contrast. Numerous questions were asked by the large and interested gathering of members, and a most enjoyable and profitable evening was spent. A hearty vote of thanks was accorded to Miss Eadon for opening her studio for the occasion, and to Mr. Lawrence and The Kodak Co. for a very good demonstration. Business was relegated to the annual general meeting which takes place next month.

A piece of white paper is put behind the negatives and the back of the frame inserted. The vignette is then adjusted by sight; if correctly placed for 1 and 3 it will also be right for the middle negative. Should inspection be difficult owing to density of the negatives, the subject can be previously outlined on the glass side with white water-colour pigment, which is washed off after the adjustment.

Printing.

If a print-out silver paper is employed, inspection in the usual way will indicate which of the negatives require printing up, the vignette openings over any negatives sufficiently printed being covered. With platinotype or allied papers a skilled printer doubtless could do the same, but large frames are awkward to handle, and in all cases small trial prints are desirable to test the vignetting. If these are exposed with a print-meter (the single-tint type being specially recommended), the exposures for the final compound print can be ascertained. Should printing be conducted by mercury light, the question is merely one of time variation. The carbon process should present no difficulty with trial pieces of P.O.P. as a guide to exposure, but has not been tried by the writer.

The way in which the negatives are inserted has already been mentioned. In the present case, negatives 1 and 3 occupy niches of their own, preventing material shift, but it is obvious there is nothing to indicate the correct position laterally of No. 2, which is free to slide either way, and requires registration as described, and also affixing by gummed slips. The registering lines *a*, *a'*, *b*, *b'*, ensure the printing paper being replaced in the same position after it has been removed on a change of negatives.

Remarks.

The foregoing method may seem somewhat formidable, and although no difficulty arises in setting-up, it certainly does take some time, but time well spent if certainty of results and ease of printing be considered; moreover, five or six negatives can be dealt with as easily as three.

A question may naturally arise: why employ daylight printing papers for the job when bromide papers, affording more facility, are available? The answer will largely depend upon the printing medium generally employed, and, possibly, to some extent upon the price charged. As a prominent professional and keen business man put it to the writer: "I really haven't the face to charge several guineas for a worked-up multiple vignette, and supply it, maybe, on precisely the same paper as used by the cheap studio over the way."

E. A. S.

RESTRICTION OF IMPORTS.—Lord Parmoor, in the House of Lords on August 6, asked the Government under what authority the executive had placed an embargo on the importation of goods and commodities other than arms, ammunition, and gun-powder. He said that in the "Board of Trade Gazette" there was a very wide range of goods or commodities which could not be imported into this country without a licence. In his opinion it was not right that the executive Government, by its own operations, should be able to discriminate and give licences to some traders and refuse them to others, because that power was undoubtedly capable of corruptive use. The system tended to keep up prices, which was one of the most fertile causes of industrial unrest. Lord Emmott asserted that protection by prohibition, subject to licence, was the very worst form of protection that could possibly be devised in time of peace. Lord Somerleyton replied that the restrictions on the importation of goods were imposed by Royal proclamation, the Act under which the proclamations were drafted being the Customs Consolidation Act, 1876. The Law Officers of the Crown had advised the Government that the words "any other goods" in that Act ought not to be treated *ejusdem generis* as "arms, ammunition, and gun-powder," and that the present restrictions on imports were within the law.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
 The Camera and the Lens (Jan. 10).
 Managing the Sitter (Jan. 17).
 Backgrounds (Jan. 24).
 Studio Exposures (Jan. 31).
 Artificial Lighting (Feb. 7).
 Printing Processes for Portraiture (Feb. 14).
 Studio Accessories and Furniture (Feb. 21).
 The Surroundings of the Studio (Feb. 28).
 Studio Heating and Ventilation (March 7).
 The Postcard Studio (March 14).
 The Printing-Room (March 21).
 About the Reception Room (March 28).
 Home Portraiture (April 4).
 Portable Studios (April 11).
 Copying (April 18).

Handling the Studio Camera (April 25).
 More About Lenses (May 2).
 Enlargements (May 9).
 Advertising the Studio (May 16).
 Mounts and Mounting (May 23).
 Business Methods (May 30).
 Photographing Children (June 6).
 Portraits of Elderly People (June 13).
 Something about Lenses (June 20).
 Hand Cameras for Professionals (June 27).
 The Dark-Room and Its Fittings (July 4).
 Plates and Their Work (July 11).
 Apparatus Repairs and Renovations (July 18).
 Posing the Head (July 25).
 Intensifying Portrait Negatives (Aug. 1).
 Workshop Jobs (August 8).

THE PERSONAL FACTOR.

If a photographer wishes for the best possible results from his business he must be able to do more than merely take photographs; he must sell them, and, further, he must, in the majority of cases, sell them before he takes them. Probably in no calling save that of a medical practitioner's does personality count for so much as in portrait photography. The doctor must inspire confidence by having a good "manner." If he is a little brusque, it does not materially affect the cure, but the expression evoked by the photographer is perpetuated in the portrait, and no amount of manipulative skill will destroy a glum or bored look. I have known several good, sound craftsmen who have struggled on for years, turning out excellent prints, but never making headway. The reason was almost identical in each case. One was more suited for an undertaker by temperament, though I am told that undertakers off duty are jovial souls. Another was apologetic in his demeanour towards his clients, while a third always gave the impression that he had been interrupted in some tremendously important work. All these failed to realise, or perhaps they were constitutionally unable to act up to it that to be successful the portraitist must be "all things to all men."

The standard of good manners is not the same in all localities, but it may be taken that it is always safe to treat even the humblest sitters as if they belonged to a much better class. They appreciate it, and applaud the judgment of the photographer, perhaps to the extent of increasing their order forthwith. If, on the other hand, really first-class people turn up, and in country districts the photographer meets with every grade, there should be no display of servility, no fussing round, with "my lord" or "my lady" interpolated in every sentence. Good manners should be backed up by a good appearance. The words which Shakespeare puts into the mouth of Polonius cannot be improved upon as advice to a business man: "Costly thy habit as thy purse can buy, yet not expressed in fancy, for the apparel oft proclaims the man." Let me hasten to explain that this does not mean a velvet jacket and a flowing tie. One must establish a cult before these can be indulged in nowadays, and even then I don't think that there is much money in it. The average

sitter, whether citizen or Society lady, feels most confidence in a well-behaved man whom one might meet on 'Change or in the Park. Once this idea of personal neatness is adopted, it will naturally spread to its immediate environment, and an untidy studio or reception room will become unthinkable. Our photographer, although possessed of a considerable amount of firmness, must yet be pliable as far as the wishes of his clients are concerned. Some men will be simply rude, perhaps, without knowing it when a customer makes what he considers an absurd suggestion. Such should be received as worthy of consideration, but difficult, if not impossible, of execution, and a very different impression will be produced.

A failing with many photographers is that of trying to please their customers by promising prints at an impossibly early date. This shows weakness of mind, and a desire to avoid immediate unpleasantness. If a photographer is honest, and tells a sitter that he can supply no more portraits for delivery (say) before Christmas, it does not follow that he will lose the order. As a matter of fact, a lady said to me, in such circumstances, "Well, if I went to someone else, they would probably promise, and not send them. I will sit now, and send them in the New Year." If I had promised and not supplied she would have had no opportunity of sending any other souvenir at Christmas, as she probably did.

Besides customers, most photographers have other folk whose goodwill has to be obtained and kept, and these are his assistants. If there is a thorough feeling of *esprit de corps* throughout an establishment, it means much not only in comfort of working, but in actual cash. Waste and delay are avoided, and if any special effort is needed, it will be made cheerfully. A well-trained staff does not want familiarity from the principal, but it appreciates consideration, and when there is a fitting opportunity a little generosity, either in the way of a cash bonus or an excursion or garden-party, not at the expense of the staff, but as a graceful act on the part of the one most interested.

Thus, what is wanted is a sedulous cultivation of the art of "getting on" with people, no matter in what way they are encountered. It is not easy to learn, but if the need is always kept in view, some measure of success is certain.

PRACTICUS.

THE FUNDAMENTAL LAW FOR THE TRUE PHOTOGRAPHIC RENDERING OF CONTRAST.

[The following paper by Dr. Alfred W. Porter and Dr. R. E. Slade is almost the first to be published as the result of the establishment of the British Photographic Research Association, in which Dr. Slade is Director of Research. By reprinting it from the "Philosophical Magazine," we wish to mark our desire to include within the pages of the Photographic Press original papers such as it, which contribute to the advancement of the scientific treatment of photographic problems. EDS. "B.J."]

The modern treatment of the character of a photographic plate is based entirely (in England, at any rate) upon the method of examination introduced by F. Hurter and V. C. Driffield in a paper read before the Society of Chemical Industry and printed in their journal dated May 31, 1890. The advance that was made by these authors was so great and the utility of their method so advantageous compared with previous methods, that the whole photographic world has joined in according them the honour due to their insight into the problem.

Nevertheless, a certain *malaise* is often felt in regard to the logical foundation of their method. Perhaps they themselves are to blame for this, because one of the important steps in their chain of arguments is made in so cursory a fashion (in a single sentence) that any reader must simply assume it to be correct unless he himself develops the argument in all its detail from the beginning.

The whole argument is this*—“Since the density is the logarithm of the opacity, and since in a theoretically perfect negative the opacities are directly proportional to the intensities of the light which produced them, it follows that each density must be proportional to the logarithm of the light intensity which produced it.” They add, in brackets: “More correctly the density is a linear function of the intensity of light and time of exposure.”

Unfortunately, in making this detailed examination, one of us (A. W. P.) has recently discovered that their principal conclusion is erroneous when regarded as a general principle. We shall first of all describe such a detailed examination and then discuss in what respects difference is found from Hurter and Driffield's results.

The problem deals with the taking of a negative followed by the printing of the negative on to another plate or paper, and investigates the conditions under which the final positive gives a true rendering of the contrasts in the original subject. There are several parts to it.

When the plate is exposed to the subject (exposure = E_1) a certain density of deposit is produced, and the negative has a certain transparency T_1 in consequence after development.

Taking stage.

Fig. 1.

In the second place, a print is made by exposing the positive plate (or paper) through the negative. Let the printing light be P . Where the transparency is T_1 , the light getting to the negative is $PT_1 = E_2$; this exposes the positive, producing a transparency T_2 after development.

Printing stage

Fig. 2.

Finally, this positive is viewed under an illumination V (the viewing light), and the light that issues from it is $VT_2 = I$.

Since for a true rendering of contrast it is necessary to have the same ratio between light emitted from two portions of our final

picture as that which fell in the camera from the two corresponding portions of the subject, we must have $I = KE$ where K is a constant reduction factor. Now, this relation between the first and last

Viewing stage.

Fig. 3.

lights concerned in the process involves a connection between the relative transparencies of the positive and negative plates. Hurter and Driffield defined the transparency T as $\frac{\text{Light transmitted}}{\text{Light incident}}$.

They also make use of a correlative quantity, the *density* D of a plate, the connection between these quantities being

$$\log \frac{1}{T} = \text{density} = D.$$

It should be observed that since T is always less than unity, its reciprocal $\frac{1}{T}$ is greater than unity and its logarithm is positive.

Now, $I = VT_2$, from the definition of transparency.

But if also

$$I = KE_1,$$

we have

$$\frac{E_1}{T_2} = \frac{V}{K} = \text{constant} \dots \dots \dots (1)$$

Similarly,

$$E_2 = PT_1,$$

whence

$$\frac{E_2}{T_1} = P = \text{constant} \dots \dots \dots (2)$$

The first of these equations states that the transparency of the positive must bear a constant proportion to the light from the subject at all corresponding points. The second equation states, what is only the direct result of definition, that the light transmitted by the negative is proportional to the transparency of the negative itself. Both of these equations must be caused to be true simultaneously by a suitable choice and treatment of the two plates.

To examine these equations further it is convenient to take the logarithms (to base 10) of both sides of each, and write

$$D_1 = \log \frac{1}{T_1}, \quad D_2 = \log \frac{1}{T_2},$$

whence from (1)

$$\log E_1 = \log \frac{V}{K} - D_2 \dots \dots \dots (3)$$

and from (2)

$$\log E_2 = \log P - D_1 \dots \dots \dots (4)$$

Let us suppose that the connection between D_1 and $\log E_1$ is known. It is represented graphically by the characteristic curve usually obtained for a plate (Fig. 4).

The above equation will enable us to determine the values of D_2 and $\log E_2$ for a plate that will form a suitable positive. Such plates which suit one another as negative and positive we may advantageously refer to as *conjugate* plates. The former equation (3) asserts that we can obtain a suitable value of D_2 by taking any constant (the same for all points) and subtracting $\log E_1$ from it. This is equivalent to shifting the origin to any point O' and measuring D_2 backwards from it; thus if OM represents a particular value of $\log E_1$, then $O'M$ represents the suitable value of D_2 . On the other hand, the second equation (4) asserts that the suitable value of $\log E_2$ is obtained by taking any constant (the same for all

* Journ. Soc. Chem. Ind. May 30th, 1890.

points) and subtracting D_1 from it. This is equivalent to still further shifting the origin to any point O'' and reckoning $\log E_2$ downwards from it. Thus if $O''N$ represents the value of D_1 , then $O''N$ represents the suitable value of $\log E_2$. Hence the same point Q represents not only the corresponding values of D_1 and $\log E_1$, but also, when measurements are made as indicated from the new origin O'' , it represents the corresponding values of D_2 and $\log E_2$. Since this can be said for every point Q in the characteristic curve for the negative, it follows that this curve suitably interpreted gives

Fig. 4.

the characteristic of the conjugate plate also. We may express the transformation most easily by saying that if the characteristic curve D_1 , against $\log E_1$, be drawn on tracing paper and be then viewed from the back so that the first origin O is at the top right hand corner, the curve, as it then appears, is the characteristic curve of the conjugate plate. Such a curve is shown in Fig. 5 for comparison.

Fig. 5.

It should be carefully remarked that the new origin O'' may be any point whatever. But it must not be forgotten that the constant amounts by which it is shifted in the two directions are connected with the viewing light and printing light. In fact,

$$OO' = \log [\text{viewing light} \div K] = \log V - K,$$

$$O'O'' = \log [\text{printing light}] = \log P.$$

To choose the point O'' is equivalent to deciding upon particular values for the printing and viewing lights and the reduction factor K . The more nearly K is to unity the more nearly will the light from the positive be not only the same in gradation as that from the subject, but also the same in absolute intensity.

When we make a print we arrange our exposure so that the curve of the paper is in the best position with reference to the axis of $\log E_2$ to be brought by development to fit the conjugate curve; then we develop until this fit is obtained. We must not develop longer or this fitting of the curves would be spoiled.

In what respects do these conclusions differ from those of Hurter and Driffeld? Their great conclusion was that it was necessary and sufficient that D should be a linear function of $\log E$ for a sensitive plate, i.e.,

$$D = \gamma(\log E - \log i).$$

This conclusion appears to have been arrived at by considering a single kind of plate only for both negative and positive, but they do not state exactly what assumptions they made. If we derive from our general results, this case in which the two plate curves by supposition are identical, it follows that

$$D = \log E - \log I$$

for each; or, in other words, γ can only be equal to unity. No other curve but this can fit its conjugate. Hence the conclusion that γ may have any value in such a case is erroneous. In a later paper* on the relation between photographic negatives and their positives, they carry the question further and conclude that

$$D_2 = \gamma(\log P - aD_1),$$

which is somewhat similar to our fourth equation; but they only give arbitrary values to a , and the value of γ is also quite arbitrary.

Fig. 6.

It would seem, then, that as the result of a somewhat quick judgment they were led to an imperfect conception of the true conditions for securing a true representation of gradation. The true result is in one case mere special than theirs because for similar plates the value of γ must be unity; it is also more general than theirs because we are not constrained to keep to the linear function at all. We will examine in detail some particular cases.

Case 1.—Suppose we follow the customary theoretical practice

Fig. 7.

and restrict ourselves to a negative in which the straight portion of the characteristic has been utilised. So that

$$D_1 = \gamma(\log E_1 - \log i_1).$$

By plotting Fig. 6 and viewing from the back it is seen at once (Fig. 7) that for the positive the necessary conjugate relation is

$$D_2 = \frac{1}{\gamma}(\log E_2 - \log i_2).$$

The constant $\log i_2$ is arbitrary, as we have said before, and $\gamma = \tan \theta_1$.

A low characteristic curve for the negative requires a steep

* Journ. Soc. Chem. Ind., February 28, 1891.

characteristic curve for the positive print. In fact, $\theta_1 + \theta_2 = 90^\circ$, where θ_1 and θ_2 are their respective inclinations to the horizontal exposure axis. In real cases, only the central part of the curve is straight (Figs. 4 and 5). Since the conjugate curve is obtained from the curve of the positive simply by a change of origin and axes, the length of the straight line portion in the two curves is the same, although the projections on the exposure axes are different in the two cases unless γ is equal to unity. Hence, in order that the two plates may match, the straight parts utilised in each characteristic must be the same in length. Generally this is possible in lantern slides or other transparencies. In the case of paper the straight line is very short; it is therefore only the gradations corresponding to a portion of the curve for the negative which will be correctly rendered. The particular part reproduced correctly depends on the printing exposure. Whether any part is correctly rendered depends on the development, for the development factors must be made reciprocals of one another (γ for the one and $\frac{1}{\gamma}$

for the other). These considerations show that if the subject presents a wide range of gradations and it is treated so that these correspond to the straight part of the curve, then development of the negative should be stopped early, so that the straight part utilised is as short as possible (for γ increases with development). The print then should have a high γ , which may be obtained partly by choice of plate or paper and partly by prolonged development, so as to make the paper curve as long as possible. For subjects with only a small range of gradation these considerations are of less moment. The three curves in Fig. 6 all correspond to the same range of gradation in the subject; with increased development the straight part required increases. The corresponding portions of best positive curves which require to be straight are shown in Fig. 7. The lines *a*, *b*, *c* on Fig. 6 require to be matched by the corresponding lines *a*, *b*, *c* on Fig. 7. Since the straight part on paper curves is short we require the part of the curve on the negative corresponding to extreme range of exposure to be as short as possible—i.e., we require the negative to have a small γ ; consequently the print must have a big γ .

This conclusion is at variance with that arrived at by Jones, Nutting, and Nees ("Photographic Journal," liv. p. 342, 1914). They point out that the latitude of plates may be as high as 12x in exposure units, although the contrast in most subjects is not more than 1 to 34; they conclude that the negative is easily capable of satisfying what is required of it. But a paper has only a latitude of 5.6 exposure units (.75 in $\log E_2$), and they say: "The paper, then, will only render correctly a range from 1 to 5.6; hence it is obvious that in order to render a negative having a range wider than 1 to 5.6 in transmission, it is necessary to utilise portions of the characteristic curve lying outside the latitude of the paper and thus depart from direct proportional rendering."

This conclusion on their part illustrates a prevalent fallacy that the range of contrast on the exposure scales of the negative and of the positive must be alike. Consider, however, a paper for which the latitude is 0.75 in log units and for which γ_2 is 1.5. This is shown in fig. 8, where

$$\tan \theta_2 = \gamma_2 = 1.5.$$

The curve of the negative which will be correctly printed by this paper under these conditions has $\gamma_1 = \frac{1}{\gamma_2} = \frac{1}{1.5} = 0.67$, and reproduces a range *ab* on the $\log E_1$ scale which is given by 0.75 $\tan \theta_1 = 0.75 \times 1.5 = 1.12$. This corresponds to a ratio of 1:13 in exposure units. Thus though the exposure latitude of this paper is only 1:6.6, it will correctly reproduce a latitude in the camera exposure of 1:13 and not only the 1:5.6 as these authors take for granted.

Case II.—It is not compulsory, however, to work in the straight portions of the curve as Hurter and Driffield thought to be necessary. Examination of the curve B'B in fig. 9 will show that this possible extension is of limited availability. No sensitive material known will yield such a curve as is shown in this figure throughout its whole length; but this is necessary to give a true photographic reproduction.

In fig. 9 we see that the curve of the paper *pqr* will fit over a certain range of the conjugate curve B'B. Thus we can reproduce

correctly over a short range of contrasts in the original by using both the under exposure portion of the negative and of the positive printing process. This portion of the curve is often used in practice, and the two curves BB' and *pqr* shown in fig. 9 are actually those of an Ilford Empress plate and a piece of Illingworth Slogas paper (Vigorous) respectively.

Again, for over-exposed negatives, the shape of the conjugate

Fig. 8.

curve is A'B' (fig. 9). We can only get the over exposure portion of the curve of a print to be of this shape. Moreover, such prints would not represent any portion of the original subject by white paper, and therefore such a print is usually of no pictorial value.

When this paper had been drafted and while it was being copied out, our attention was called to the Traill-Taylor Lecture, given by Mr. Renwick in 1916, in which the same question of matching the negative and positive is discussed. In this lecture Mr. Renwick gives what he calls reciprocal curves for the positive and negative respectively; but he does not describe how they have been obtained. In the absence of such a description it is not possible for us to test how far his work overlaps or anticipates ours. But

Fig. 9.

he certainly does not touch the validity of Hurter and Driffield's conclusions.

We have also found a paper by Lord Rayleigh "On the general problem of photographic reproduction with suggestions for enhancing gradation originally invisible" (Phil. Mag. xxii. p. 734 (1911)), reprinted (British Journal of Photography, lviii. p. 994 (1911)). In this paper Lord Rayleigh certainly goes to the root of the matter so far as the matching of plates is concerned, but does not leave the problem in a form suitable for practice. In particular, some of the assumptions made in the typical cases taken do not fit in with practical aims. For example, there is no object in making the gradation of the negative the same as the positive. The only condition which seems to us useful is that the gradation in the issuing light (*I*) shall be the same as that from the original source (E_1). This is the condition which we have taken as fundamental.

ALFRED W. PORTER, D.Sc., F.R.S.
R. E. SLADE, D.Sc.

SOFT-FOCUS PORTRAITS.—Wanting to try my hand at soft-focus portraiture and not caring to invest in a special lens, I tried the effect of using an old portrait lens with the back combination removed. The results were surprisingly good.—A. S. D., in "Camera Craft."

SELF-TONING PAPER.

From Rajar "Trade Notes."

THE present great demand for self-toning paper prompts us to offer a few hints on its successful working. Although its keeping qualities are good, the paper should be used as quickly as possible, and if there is a slight discolouration this will be cleared away in the fixing.

Failures to obtain good colours or tones are tabulated below, the first one being by far the most prolific cause of poor tones:—

1. "Drowning" the gold that is incorporated in the emulsion by using too great a bulk of solution for the number of prints. The rule to observe is to use only sufficient fixing-solution to just comfortably cover the prints.

2. Using an old fixing-bath that has done duty for plates, etc. The hypo-solution must be freshly made, and no other ingredient added.

3. Too weak a fixing-bath. A good strength is 5 to 6 ounces of hypo to a pint of water. This gives fine brown colours on our "Autona" paper, with no trace of double tones.

4. Prolonged washing after fixing may spoil the prints. One hour in running water is ample.

For amateurs, and for dealers who specialise in "finishing" amateurs' work, the self-toning process gives beautiful prints, and provided the fixing is properly done, the results can be said to be permanent.

The time of fixing with a bath of 5 ozs. to the pint should be ten minutes at about 60 deg. Fahr. Longer immersion in the fixing-bath may reduce the prints considerably. Prints that have been over-printed can be fixed in a stronger solution, or for a longer time in a normal solution, thus taking advantage of the slight reducing action.

Some amateurs place their self-toning prints in a combined toning and fixing solution as used for P.O.P., and to these we must point out the necessity, for permanence sake, of afterwards fixing them in a bath of plain hypo (2 ozs. to the pint of water) for ten minutes.

PHOTOGRAPHIC-VISION FILTERS FOR ORTHOCHROMATIC PHOTOGRAPHY.

THE manual "Panchromatism," just issued by the Ilford Company, and the subject of reference on another page, contains a description of the new P.V., or Photographic-Vision filters, the issue of which is being made sooner than was suggested by their originator, Mr. F. F. Renwich, in the paper before the Royal Photographic Society in which the principle of the new filters was outlined. Since the practical facilities which the P.V. filters confer cannot be too fully understood, and as the latter constitute an entire innovation in orthochromatic photography, we reprint here the passage from the Ilford publication which deals with them:—

These filters are an altogether new introduction, and constitute a valuable application of colour screens to photography. The principle upon which they depend is quite easy to understand; they cause coloured objects viewed through them to assume the same relative tone values as will appear in photographic copies made by means of the plate for which the filter is designed. For example, an ordinary plate, being sensitive to blue and violet only, and blind to pure green and pure red, renders these latter colours as black; hence it has always been possible roughly to appreciate what the record of a coloured scene will be like when made on an ordinary blue-sensitive plate, by examining the scene or object through a pure blue-violet filter such as the Ilford tri-colour blue filter. If, however, an orthochromatic (green sensitized) plate like the Ilford Chromatic plate is to be used, no previously devised filter will assist the photographer to any certain knowledge of what will be the order of luminosity assigned by the plate to the various parts of the subject if he makes an exposure. This is done by the Ilford P.V. Iso filter; while, when an Ilford Panchromatic plate is to be used, the Ilford P.V. Pan filter fulfils the same function.

A little consideration will show what an extremely valuable tool such a filter is for the user of colour-sensitive plates. By mere inspection of the proposed subject through the P.V. filter he can, after a very few trials, judge fairly accurately the order in which the plate will record the colours present *when no filter is used*. He

can then proceed to study the effect of using any filter he likes to try, simply by looking through it and the P.V. filter together, and so can select for use that filter which will give him the tone relationships he prefers, without having to waste time and material on that guess-work photography which so often leads to disappointment. At first the majority of people find difficulty in deciding upon the order of brightness of a number of differently coloured things, but, provided their sense of colour is normal, this phase of uncertainty soon almost disappears, though small differences of luminosity between widely different colours are always difficult to recognise with certainty. We have no hesitation in saying, however, that our P.V. filters are a most valuable aid to the photographer even at the start, for by studying the effects produced by our Iso, Alpha, Beta, and Gamma filters on a brightly coloured test object when it is looked at through each with the P.V. filter as well, he will be astonished at the results of his observations, and will speedily appreciate the meaning of what he sees and the effects of the correcting filters. Having once grasped the meaning of luminosity (apart from colour) of a coloured object, he will then be able to select with certainty the best filter for any work on hand by the aid of the P.V. filter. >

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Some Simple Copying Hints.

OWING to the war and its losses, and the number of men and women who have now permanently put aside their uniforms, there is an immense field in copying and enlarging for the photographer to work upon; and in order to get such work through as well and expeditiously as possible, many photographers might overhaul their working methods for copying with advantage, and bring them well up to date. This would ensure better copies being turned out more quickly than before.

For one thing, the copying easel or board might be made a permanent and ever-ready fixture. A little thought given to its even illumination by artificial light would ensure that many a slack half-hour in the dark evenings would be turned to good account, and copies would not need to be kept hanging about indefinitely, waiting for a spare hour and good daylight.

The work turned out by the trade houses and by photo-engravers is really wonderful. Photographers might well take a leaf out of their books, for it is only careful thought and planning that has brought their methods up to so high a pitch of perfection. A few suggestions, therefore, may not come amiss.

Often a print is brought in for copying, and some explanatory text matter is desired to be added to it. The usual way seems to be to copy, make a rough print, add the required wording, and copy again. Usually, something of the quality is lost in each fresh negative made. Usually the print is too precious to be worked upon or tampered with. Another method might be tried, however. Get a few sheets of the very best and most transparent tracing-paper or linen, mark round the edge of the print, and cut out of the sheet. Fasten on to a drawing-board, and carefully and smoothly paint all the framework of the tracing paper with that kind of opaque white paint known as "process white," as used by photo-engravers. There is a special brand made by Windsor and Newtons, which, in my experience, seems to photograph a purer and cleaner white than any other—always a difficulty when a new negative has to be made. When this white mask is perfectly dry, add the necessary wording in "process black." When dry, carefully adjust the mask over the print to be copied, cover with a piece of perfectly clean glass, bind together with passe-partout binding, and proceed to copy in the usual way. I take it for granted, of course, that a slow or else a "process" plate is used for making the fresh negative, as they give so little grain, yield so much better results, and in case of any slight error in the exposure respond so much better to treatment during development than do faster plates.

One thing I think photographers often fail to realise, and that is the amount of time that could be saved in the finishing department if only a little more were expended on making and preparing the

copy negative. How often does it happen that something like the following takes place?

The printer or operator takes a negative to the retoucher: "Oh, Miss So-and-so, just spot this copy-neg., will you, and let me have it in a few minutes; soon as ever you can, will you?"—failing to realise that perhaps one hour of that retoucher's time spent on that one negative would save as much time spent on each one of perhaps six dozen prints in the spotting room. It is such simple logic, yet heaps of photographers don't seem to realise it. It repeatedly happens that an enlargement is first ordered, and then, perhaps, later, a few dozen contact prints; and think of the working up that might be saved if only that copy-negative had not been so rushed. Then, again, there are one or two little preparations on the market that both save time and give better results. One of these is the deep red matt varnish, which, if spread over parts that refuse to print properly white and carefully scraped away from the back of the negative to the required outline, gives far better results in a few minutes than the slow and laborious dabbing on and working down with the finger of red paint, as practised by scores of photographers. Also it enlarges infinitely better. Then such things as Billdup make it far easier to lighten a part that prints too dark, with stamping-chalk, and so on; while, after much labour expended on a copy-negative from which many prints have to be made, many photographers omit the perhaps rather bothersome process of hot varnishing, but which well repays the little extra trouble in the protection from scratches and accidental damage it affords a much valued negative.

I saw a little dodge in use some time ago which struck me as being very clever. We all know the great risk there is in copying delicate platinotype and carbon prints, from which, perhaps, one figure has to be taken out of a group and part of a figure worked in. Well, the method I saw was as follows:—A number of carbon prints needed this treatment, and each one was covered with a piece of the finest quality clear celluloid lightly fastened to it with gummed strips. The blocking out was then done on the celluloid cover with very smoothly mixed oil-colour and finest sable brushes, so that practically no brush strokes showed. Backgrounds were added and covered up; legs added and hands blocked out in this way in comfort, and with no risk to the prints. They were then put up and copied in the usual way on non-screen plates, and I was very surprised at the excellent results obtained. Then, once the negatives were made and passed, the celluloid was very gently washed with best turps and cotton-wool and was ready for use again, so long as no scratches showed. There is also a special kind of transparent paper made for the use of photo-engravers, and called, I believe, "Irisket" paper, which would probably serve the same purpose.

Where cloudy effects, etc., are wanted in backgrounds and no air-brush is available, a quick method is to use a stiff tooth-brush dipped in the required colour and held bristles down over the part of the print to be covered. The bristles are then scratched towards the user with a match or brush handle, which makes them shoot out a fine spray of colour in tiny spots. A little preliminary practice should be tried to get the knack of the thing, but it is really very often quite a quick way to cover a large space. Water-colour, of course, should be used, made up in bulk ready for use in a saucer.

Where wording of a small size has to be put in or under a print, and is done by the finisher, it could often be better done with black waterproof drawing-ink and a pen which is fairly thick and does not smear, than by the water-colour and brush method usually employed. There are also little handbooks of the letters of the alphabet in all styles of type, published by Vere Forster and, I think, George Rowley, which are sometimes a most useful guide to the perplexed finisher, who must put dates, titles, etc., on albums of finished copies and mounts and outside covers, and all these details help to make copying both more paying, satisfactory, and easily accomplished. In the absence of an enlarger, a pantograph is a useful little tool, used, of course, with a blunt point—say a brush handle or bit of stick in lieu of the pencil, to give the exact size to which a figure should be enlarged, reduced, or photographed, for inclusion in a group and any similar thing, or for making a mask to use in combination prints, and so forth. A few thicknesses of

matt celluloid are also sometimes useful when printing on bromide paper from a poor negative, when no slow paper is at hand, and will avoid intensification when this is not possible. It is so free from grain that it is better than matt varnishing or the use of tissue paper.—G. E. H. G.

Press-Photographic Jottings.

News items, opinions, etc., expressing the interests of press photographers will be welcomed by "Ranger."

FLEET STREET—the Fleet Street of Press photographers—is awake again. Many of its well-known camera men have returned after years of naval and military service. I notice that Messrs. B. and T. Grant have returned to the "Daily Mirror," also Messrs. Castle and MacLellan. Mr. H. Baldwin, formerly Australian Official Photographer, has established his own business in Fleet Street. R. Silk is with the "Daily Mail"; G. Limbery and H. Outram have opened larger premises in Johnson's Court, near to Richardson, late of the R.A.F.; Rider, Rider, and Brooke, late official photographers, are now busy again in Fleet Street.

Now that the official photographers have returned, what will be their reward in the shape of decorations? There is no doubt that their work was very arduous and dangerous. We must not forget the loss of a leg by Mr. A. Console, the illness of Mr. Brooke, and the discharge of Mr. H. Baldwin on the ground of ill-health. It should be the part of someone in authority to get them public recognition, first from the British authorities, and then from the Allies. Inasmuch as official war photographs were enjoyed by millions throughout the world, surely their makers should be recognised?

Many of the boys are having a very "cushy" time just now at the seaside, combining business with pleasure. During August there is always a good demand for bathing pictures. It is by no means an easy job to think out fresh "stunts." The mere group of bathers, or overbacks, is played out. Certain it is that American picture papers make a better show of this class of illustration than we do.

One does not realise the number of cameras which are in daily use. The Cenotaph, with its base covered with flowers, has been photographed at the rate of about 100 cameras per hour. Soldiers, sailors, girls, men—all classes of people—have been among the photographers.

Police permits for photographers are now being issued to professional Press photographers. Each permit is a folder bearing the holder's photograph, and certifying that the bearer is an accredited and responsible photographer, and is recommended for all facilities. It is signed by Sir C. Nevill Macready and Sir J. N. Nott Bower.

A recent reproduction in the "Daily Graphic"—showing about ten camera men "taking" a bride and bridegroom—raises a nice point as to whether it is quite dignified for the operators to be jostling one another amongst the tombstones—or so it seems.

Press operators have had a very busy time just lately. How many have received double pay for working on Peace Day?

Almost all the newspapers still keep up their war prices: there is no likelihood of a return to the halfpenny pictorial, which makes one ask—When are photographers going to increase the minimum reproduction fee? Some of the Press Agencies have put up their fees, but I don't think it is general.

I wonder when British camera makers are going to produce a new 5 x 4 or 1/4-plate folding camera with a lens working at $f/3$ and of 7 ins. focal length? Something light, serviceable and strong, with single slides.

RANGER.

Photo-Mechanical Notes.

Photo-Engraving Stencils.

Do any readers know exactly how reproductions are made by stencil in somewhat the same way as a typewriting stencil is made? We understand a piece of muslin is taken and covered with a solution of bichromated gelatine. Then, after it is dry, an exposure is made to a positive, if a positive is required, developed in water, fastened to a frame, paper placed underneath, and an ink roller applied. The insolubilised gelatine prevents the ink going through in parts, but it can get through the muslin where the colloid has been dissolved away, namely, the places that were under the black image of the positive. This would seem to be a perfectly practicable process for line drawings. Has it ever been used for half-tone with success? And what is the formula for the sensitizing solution?

Labour Shortage and Its Effects in America.

At present in both the United States and Canada there is a demand for engravings that is almost beyond the capacity of the business to take care of with the amount of labour available. This has led to high wages and to employers tempting men from one establishment to another by the offer of still further increases. So that the retention of the labour force has become a problem which at least two of the firms in the Middle West are attempting to solve by introducing the shop committee, and sharing profits. The committee elected by the men are allowed to formulate their own working conditions and suggest their remuneration, which, however, is not much, if any, above the standard rate—the standard rate being in most towns very considerably above the trade union minimum just now. Their incentive to production and loyalty comes from the share of the profits they are entitled to. The method so far adopted is to establish the value of the capital of the firm, which is preferentially entitled to 8 per cent, and after this is paid the remaining profits are divided among the staff. There is no doubt that this is an entirely satisfactory scheme so long as business is brisk and the management from the selling end is thoroughly competent. But if the selling should be incompetent, or some accident, such as bad debt or a fire, should wipe out the profits, it is doubtful if the workpeople, who have put extra effort into their work in anticipation of extra reward which will not be forthcoming in such case, will be quite so satisfied.

It has always seemed to the writer that profit-sharing is not ideal from the workman's point of view, because so many elements over which he has no control may enter in to vary the amount of profit and consequently render futile his extra diligence, so that he is soon likely to get into his previous habit of taking things fairly easily. Moreover, the payment of profit is usually so far distant from the time that it is earned, that the connection between the work and its reward tends to disappear. On the other hand, a system of bonus on production is difficult to apply in complicated work like photo-engraving, where each piece differs from every other, and two pieces apparently exactly alike may require very different amounts of labour to be spent on each to produce a saleable result. As the processes become more and more subdivided, these differences tend to become less, and if the bonus was reckoned over a large number of engravings they would average out. Any shop introducing a bonus system would have to do a considerable amount of work in standardising methods, and make very careful studies as to what is a fair day's work for the normal standard wage, on top of which they would pay the bonus for extra production.

In any case, it is clear that something has to be done, for it is apparent that a loyal and contented staff cannot be retained in present circumstances unless they have some share of the management, at all events so far as concerns their working conditions, and some incentive not to "ca-canny."—A. J. N.

A GOOD RETOUCHING MEDIUM.—The best retouching medium that I have ever used is one that I got from a demonstrator about five years ago. It is made as follows:—Red rosin, 3 ozs.; turpentine, 6 ozs.; sulphuric ether, 2 ozs.; beeswax, 30 grs. The rosin is dissolved in the turpentine by means of gentle heat, and to this is added the beeswax, previously dissolved in the ether.—G. T. B., in "Camera Craft."

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications July 28 to August 2:—

SHUTTER TESTER.—No. 18,680. Testing speed and effectiveness of photographic lens shutters. H. A. Cummins.

PRINTING.—No. 18,699. Photographic printing. W.V.D. Kelley and J. Mason.

DEVELOPING AND FIXING.—No. 19,000. Apparatus for developing and fixing photographic films. A. R. Turner.

COMPLETE SPECIFICATIONS ACCEPTED.

ROLL-FILM.—No. 122,391 (June 9, 1917). The invention consists in providing a light-excluding wrapper (for roll-films, pack-films, etc.) having a waterproof coating in its inner surface, *i.e.*, in the surface which comes in contact with the non-sensitive side of the film; or with a waterproof coating on both sides. Both sides of the light-excluding paper are waterproofed, so that it may not give off anything that might impair either the face or back of the film, and the rear face of the film is waterproofed to prevent it from absorbing any matter which might stain or discolour it. As the film must, when developed and fixed, be transparent, it is necessary that the water-proofing composition should be transparent, and it is likewise important that it be highly flexible and quite tough or tenacious, so that the film may be rolled upon a spool, or wound from one spool or reel to another without breaking, cracking or reeling off. Nitro-cellulose is found to fulfil admirably these conditions, but other water-proofing agents may be used if preferred, as, for instance, cellulose acetate. Arthur Williams McCurdy, 83, Crescent Road, Rose-dale, Toronto.

TRIPOD STANDS.—No. 129,601. (March 15, 1919.) Each leg of the improved stand is made up of three sections, the two upper sections being of a channel formation, being each formed with a longitudinal groove respectively along their entire length. The middle leg section, which is preferably made of wood, is adapted to slide within the groove in the upper section (which may be made of sheet-metal) when it is desired to collapse the stand, the lower member of the leg (preferably in the form of a metal tube) being arranged, in a similar manner, to slide within the groove in the middle section, so that the three sections telescope one within the other. In order to hold the middle section rigidly in its extended position it is provided at the upper end of its inner face with a central screw or stud which is adapted, on the middle section being fully extended, to engage within a slot formed in a metal plate attached by bent-over ears to the sides of the lower end of the top section. On the stud entering the slot the two upper members of the leg are rigidly held together and any side-play prevented. To hold the lower leg-section, which is of a circular cross-section, in its extended position and to prevent any rotation or side play a similar arrangement is employed, the upper end of the bottom section being provided with two longitudinally separated screws or studs adapted, when the section is extended, to engage with a longitudinal slot in a metal plate, the latter being provided at each side with a pair of bent-over ears whereby it is attached to the lower end of the middle section of the leg. James Ashford, Aston Brook Street, Birmingham.

SHOCK-ABSORBERS FOR CAMERAS.—No. 129,011 (Sept. 19, 1917). For the support of cameras attached to aeroplanes and in other positions where they are exposed to vibration, a flexible chamber or enclosure is used filled with aerated rubber cuttings (sponge rubber).

The method of making such shock-absorber consists in providing a rectangular block of wood or other material provided with transverse grooves, encircling the block with a band of fabric, placing resilient tubes in the bottom of the grooves, fastening them in place with thread and end buttons, removing the block.

attaching a bottom to the band of fabric, and filling the band with cuttings of resilient material. William Johnson Greer, 18, Chiswell Street, Finsbury Square, London, E.C., and Luther Archibald William Martin, 77, Tavistock Avenue, Walthamstow, Essex.

PHOTOGRAMMETRIC CAMERAS.—No. 119,033. (Sept. 2, 1918). In photogrammetric apparatus it is known to use a cross of wires, hairs or fibres close in front of the sensitive plate or film. The vertex of the cross lies in the optical axis of the photographic lens and the cross is taken directly upon the picture when the photograph is taken. Crosses of wires, etc., have, however, the disadvantage that when the apparatus is applied to a vehicle, i.e., to an aeroplane, it is subjected to vibration, so that the cross is not fixed upon the picture with the desirable accuracy and sharpness. This disadvantage is avoided by a cross consisting of metal strips having their widths perpendicular to the focal plane. Into the rear extremity of the camera is set a cross formed by metal strips, in front of the focal plane in such a manner that the angular point of this cross lies in the optical axis. It will be seen that when taking a picture this cross and therewith the optical axis are taken upon the picture, the coincidence of the angular point of the cross with the optical axis being guaranteed once for all. Nicola Stefani, Calprino, Tessin, Switzerland.

LANTERN SCREENS.—No. 128,873 (Feb 21, 1919.) Fabric is first treated with size solution and then with asbestos in paint form. It is claimed that the pores of the fabric are filled so that it becomes light-proof and the lines of the fabric are obliterated.

The screen is then treated with a mixture of gold size, terebene, turpentine and aluminium powder in paint form to produce a silver white surface. Robert Gilpin, 22, Holmwood Villas, Gander Green Lane, Sutton, Surrey.

AERIAL CAMERAS.—No. 128,637 (Aug. 20, 1917). The camera comprises mechanism for giving an intermittent movement to roll-film and for automatically protecting the film from light-action when in motion. The core of the film-roll is of such size that the first lap of film around the core will constitute an integral number of pictures or a single picture. The take-up roll is intermittently rotated by means operable from a continuously rotating spring-actuated shaft, and the shutter mechanism comprises an endless apertured blind intermittently movable. The film during the periods of movement is between the apertures in the blind and back thereof, and an aperture of the blind successively exposes portions of the film during the periods of rest of the film. There is a fluid-carrying chamber having connected ports adjacent to opposite ends, and a plunger engaging in the chamber is connected to the continuously rotating shaft to have longitudinal movement imparted thereto by the movement of the shaft during the feeding of the film and the actuation of the shutter to regulate the movements thereof through the shaft. The shaft is continuously rotated by a spring, and in which the take-up roll is intermittently rotated to advance the film by a mutilated gear fixed to the shaft co-operating with a mutilated pinion connected to the take-up roll, and means is carried by the gear to co-operate with means connected to the pinion to cause a toothed portion of the pinion to mesh with a toothed portion of the gear. Wheels are provided to support the blind, and in which the movement of the blind is controlled by escapement mechanism. These wheels are actuated to move the blind by a pinion rotatable with the shaft. A second pinion is driven through an intermediate pinion from and in the same direction as the first pinion; a gear is fixed to the shaft of the second pinion, and a pinion rotatable with one of the blind wheels meshes with the gear. The escapement mechanism is controlled by the first and second pinions to operate the gear intermittently. H. G. C. Fairweather, 65-66, Chancery Lane, London, W.C.2, for G.E.M. Engineering Company, 1216, Walnut Street, Philadelphia, U.S.A.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

CHALLENGE.—(Scotsman Design) No. 388,871. Photographic cameras. The firm trading as J. J. Lizars, 101, Buchanan Street, Glasgow; manufacturers. March 4, 1919.

OSDA.—Nos. 392,325 and 392,326. All goods included in Classes 39 and 8 respectively. The Houghton-Butcher Manufacturing Company, Ltd., Clifford Road, Walthamstow, London, E.17; manufacturers. June 14, 1919.

E. P. G. Design.—No. 391,449. Photographic paper. Eric Purslove Glover, 5, Park Lane, Leeds, Yorkshire; manufacturer and publisher of photographic specialties. May 21, 1919.

Extracts from our weekly and monthly contemporaries.

Woodland Photography.

Fog and mist are sometimes useful in summer as a means to obtain greater differentiation in tone between planes of the scene and presenting foliage in flat masses when some decorative, poster-like effect is wanted; but, as a rule, main dependence should be placed upon finding just the right angle of lighting. During the long days of summer (writes Mr. Wm. S. Davis in *Photo. Era*) the nearly vertical rays of the noonday-sun is more likely to produce a spotty effect in the foliage than earlier or later in the day. On the other hand, when the sun is very low, there may be a lack of lighter tones in dense woods—even the foreground may appear dull and heavy because of the absence of light and shadow for accents. The best hour can be found only by visiting the same spot at different times, as every composition varies somewhat in such matters as the density of foliage and grouping of trees. When the ground is uneven, the direction of its slope affects the play of lights and shadows over the surface; it is possible to obtain pleasing cast shadows on a slope facing the sun when the latter is low. On a northerly slope, one might have to work near noon-time to get any effect of light and shade. The presence of slight haze is often a great help to soften the intensity of the illumination; it keeps contrasts within more controllable limits without in any way lessening the play of light and shade characteristic of sunshine.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, AUGUST 16.

Hackney Photographic Society. Outing to Woolwich.

TUESDAY, AUGUST 19.

Hackney Photographic Society. Print Competition: "A Market Scene."

WEDNESDAY, AUGUST 20.

Tonbridge Wells Amateur Photographic Association. "Colour Exhibition." North Middlessex Photographic Society. "Landscape Photography." E. C. Ridge.

THURSDAY, AUGUST 21.

Hampshire Hobbies Photographic Society. "Photographic Chemicals." R. L. Scorgie.

CROYDON CAMERA CLUB.

Mr. C. SMYTH gave a very practical chat on the manufacture of light filters, a subject on which he is entitled to speak with the voice of authority. It was mainly a repetition of a previous discourse given some time ago; since then many new members have joined, and may live to bless the lecturer for an introduction to a craft of peculiar attractiveness. One or two of his previous audience have expressed a strong desire to apply a full measure of correction to the expert himself, as a slight return for value received.

Mr. Smyth said light filters might be considered in many aspects, but he proposed to deal only with the mechanical side that evening. Coating glass with dyed gelatine was out of the question owing to the pull on the glass which occurred on drying. Consequently, a dyed sheet of gelatine had to be sandwiched between two glasses, optical contact being obtained by cementing the three with canada balsam. He then proceeded to explain how the dyed gelatine sheets were made, evidently a job demanding long experience to avoid the many failures which threatened on all sides, one best left alone by the great majority.

Much valuable and interesting information was afforded, of

which only a few salient points can be alluded to. The chief difficulty of the novice is undoubtedly the cementing, and pools of balsam solution, often applied, tend to air bells and an unnecessary distribution on surrounding objects. He strongly recommended purchasing the day canada balsam (very expensive at the moment) and dissolving it in xylol, in preference to other solvents. The viscosity should be about half that of golden-syrup.

A thoroughly cleansed and polished cover-glass is laid on a flat surface. For a small filter a drop of the solution is placed on the centre; the film is adjusted to the glass; another drop is placed on the film, and the remaining cover-glass placed over. It is important that these operations be conducted as speedily as possible. Central pressure by a finger drives the balsam to the edges, the air being pushed in front. The filter is then dried for about a fortnight at a temperature of 80 Fah., and moderate size filters do not require any superimposed weight. Exuded balsam is cleaned off with methylated spirits; more powerful solvents should not be used as they are apt to penetrate between the glasses. Start with swansdown (washed to remove "loading") and finish with best quality tissue paper. Although Mr. Smyth omitted to say so, with the "all fingers and thumb" fraternity by this time the apparel worn during the balsaming, together with the table-cloth, carpet, etc., may have returned from the dry-cleaners and all, except the filter, will be well.

Many things also dealt with, such as the selection of suitable glass, are now quite well known, or should be, as *ex-cathedra* paragraphs have a partiality for pointing out that glass of inferior flatness results in inferior definition. Quite apart from this, in days gone by the disadvantage of putting a filter in front of the lens has been alluded to, as tending to start a game of badminton with forward projected flare spots. Others have advanced reason against placing the filter behind the lens, and insertion between the combinations may play "Old Harry" with the corrections of some anastigmats. Accordingly the only really safe position for the filter appears to be the inside of its case.

In the discussion Mr. F. C. Reynolds congratulated the lecturer on so ably filling the bill and the blackboard. He asked whether the centre of the filter ever set. Mr. Smyth replied it never went dry. (Export to U.S.A. should be prohibited). Mr. H. King, whose powers of observation are evidently not on the wane, had noticed that the price charged for gelatine film tri-colour filters were materially less than for optical flats. He found the films cockled a little, and inquired whether this affected definition. "No," said Mr. Smyth, an answer which suggests the possibility of a corrugated film filter, opening and closing in concertina fashion, and affording various multiplying factors. Mr. Cavendish Morton had observed a certain waviness in the gelatine in a set of 15 by 18 cemented tri-colour filters. The lecturer said he had stopped short at 10 by 8, presumably referring to filters, for expressed either in inches or feet, he looks neither the height nor the girth. A most hearty vote of thanks was accorded him.

Commercial & Legal Intelligence.

NEW COMPANIES.

LEONARDSON AND CO., LTD.—This private company was registered on August 5 with a capital of £3,500 in 2,000 "A" pref. shares of £1 each, 110 "B" pref. shares of £10 each, and 8,000 defd. shares of 1s. each. Objects: To acquire the business of a photo-engraver, artist, designer and technical photographer carried on by G. S. Coles at 12, Botterton St., W.C., as "Leonardson and Co." (subject to liabilities) for £1,000. The first directors are: S. Spooner, The Leys, Little Clacton, editor and journalist; G. S. Coles, 31, Holmesdale Avenue, East Sheen, S.W., photo-engraver. Registered office: 12, Betterton Street, Drury Lane, W.C.

PREMIER FILM PRINTING AND CHEMICAL CO., LTD.—This private company was registered on August 6 with a capital of £20,000 in £1 shares (10,000 pref.). Objects: To carry on the business indicated by the title. The subscribers (each with one share) are: F. J. Whitlock, 9, Bank Street, Rugby, estate agent; H. Eaden,

15, Church Street, Rugby, solicitor. The first directors are: F. J. Whitlock (chairman), H. Eaden, B. Morris and H. A. Browne. Qualification, £100. Registered office: Upper Grove Street, Leamington.

LIMITED PARTNERSHIPS.

ALLIES STUDIOS.—Photographers, 265, Kensington, Liverpool. Partnership commencing May 20, 1919, for six months certain, terminable thereafter by three months' notice. General partner: H. Apted, 58, Romer Road, Kensington, Liverpool. Limited partner: A. Keith, 31, Wheatlands Lane, Wallasey, contributing £100 in cash.

News and Notes.

MR. W. A. FURSE, for many years with the C. P. Goerz Optical Work (London) until his resignation of that position shortly after the outbreak of war, has established himself as a dealer in cameras, lenses, and other apparatus, and in the printing and developing of negatives, at 27, Chancery Lane, London, W.C.2. Mr. Furse's long experience in the sale of high-class apparatus specially qualifies him for the patronage of those who wish to buy a good article and can appreciate the advantage of going to a retailer who is himself an expert. Mr. Furse is also selling (and buying) second-hand cameras and lenses, in which branch likewise his customers will benefit by his technical qualifications. We wish him well in his business.

R.A.F. PHOTOGRAPHIC SECTION.—The first annual dinner of photographic officers of the Royal Air Force was held on Monday last at the Café Royal, Regent Street. Major F. C. V. Laws presided, and among those present were Lieutenant-Colonel Moore Brabazon, M.P., Major P. R. Burchall, and Major Gamble.

Major Laws (according to the "Times"), in proposing the toast of "The Photographic Officers," said that on the Western Front it was recognised that British aerial photography was ahead of that of all the Allied forces, and far in advance of that of the Germans. In Germany the Imperial Air Ministry issued a statement, at least six months ago, that aerial photography was a science created by the war, and they must not allow it to slip from their fingers. He hoped the British Air Ministry would appreciate the value of the science as soon as possible. Every town, river, railway, and road in the country ought to be photographed from the air.

The toast of "General Trenchard, Colonel Moore Brabazon, and the Training Division" was also honoured.

PANCHROMATIC PHOTOGRAPHY.—A publication which will contribute in very large measure to an understanding knowledge and use of panchromatic plates has just been issued by Messrs. Ilford, Ltd., as "Panchromatism." It is a twenty-four page pamphlet of folio size containing a large number of reproductions illustrating some noteworthy applications of panchromatic plates. But it will be bought and studied for its very admirable presentation of the principles and facts of colour and the relation of colour-sensitive plates and light-filters thereto, and on that account we must heartily recommend it to the notice of all who are interested in sharing the photographic triumphs which the panchromatic plate puts easily within reach. Incidentally the monograph is a demonstration of the very great advance in the manufacture of panchromatic plates made by the Ilford Company in their "Special Rapid Panchromatic," an advance which does much to remove the prejudice against panchromatics existing among photographers who are not compelled to employ them by the fact of competitive results made on them. The treatise sets forth the disabilities attaching to the use of panchromatic plates, and thereby makes them look small in comparison with the benefits obtained. It also contains a description, part of which we quote on another page, of the new means in the shape of "photographic-vision" filters by which the need of judgment or guesswork is in very large measure removed from the use of panchromatic plates and light-filters for correct translation of colours into monochrome. This is a new power which will be appreciated as much by the landscape photographer as by the professional copyist of paintings and pottery. The booklet, inclusive of a colour test chart for use in tests of particular combinations of plate and filter, is issued at 6d., post free 9d. It must cost several times this amount to produce.

Correspondence.

- Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- We do not undertake responsibility for the opinions expressed by our correspondents.

A TEMPORARY FOCUSING SCREEN.

To the Editors.

Gentlemen,—A simple method of making a screen, which, while it may be properly termed temporary, will last quite a long time, is to rub paste smoothly over a piece of glass; when quite dry rub over a very small quantity of oil. This will be nearly equal to ground glass.

E. A. NORTON.

CO-OPERATIVE HOLIDAY CLOSING OF STUDIOS.

To the Editors.

Gentlemen,—I do not quite see how all photographers can afford to close their studios for a whole week, and that at a time when every other business is on holiday. In some studios, where the clientele is more or less of the moneyed or leisured classes, and a large number of hands are employed, the plan of closing for a week is undoubtedly the simplest and easiest way to give all employed their holiday with the least interference with business.

Also, the studio that depends largely on factory workers, when the bulk of the sittings are on a Saturday, may quite easily close during the general holiday, as the hands mostly spend their money on trips, etc., and wait until afterwards to get photographs taken.

But there is one thing that seems to be forgotten in this holiday question. Owing to the Early Closing Order, every studio has to close at the same time as the shops of grocers, drapers, and various other trades, and the assistants and others employed in these businesses are never at liberty except when the studios are closed. Another thing that should be altered is this: Instead of advertising that the principal studios of — will be closed, and not taking the trouble to ask all the photographers to join in, those who want to close should put their names to the advertisement, as some of the shopkeepers do, so that the public may know whose studios they are.—Yours faithfully,

SINGLE-HANDED.

[The above letter was unfortunately received just too late for appearance last week.—Eds., "B.J."]

FEDERATION AND THE P.P.A.

To the Editors.

Gentlemen,—I have to thank Mr. Fry, hon. secretary of the P.P.A., for his courteous rejoinder to my query as to whether "the Council of the P.P.A. are alive to their responsibilities," and I will promise him that when we have our next district meeting his offer shall be considered and acted upon.

Mr. Fry, speaking for the Council, is in agreement with us as to the value of local and district associations in all matters affecting the interests of photographers in definite localities.

When possible, these should be organised and managed by members of the P.P.A., and one suggestion I would make is that such association should have, in due time, direct representation on the Council of the parent association, with the status of accredited branches.

I know these and similar suggestions were discussed in the good old convention days, when the ordinary and obscure provincial member was permitted to rub shoulders with the "big wigs" of London town, but the war has set back all those schemes of development and made the work of the Council difficult and perhaps disheartening.

However, we look for a return of the conference next year, and in the meantime let photographers in each district get together in the early autumn and form real live groups of hearty co-operation, knowing that if they prove themselves worthy of recognition the Council of the P.P.A. will receive them in fellowship and reward their endeavours, perhaps in the way I have suggested.

The P.P.A. should by this time be a strong federation of numerous county and district associations, instead of practically a small executive, the members of which to a large extent represent no one

but themselves, and I say this in no disparagement of the service they seek to render to the general body of members.—Faithfully yours,

S. H. GREENWAY.

Abington Street, Northampton.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

- J. COOK, JUN.—Yes, by pressure in press at a greater heat.
- K. K.—We certainly think that the starting of a business in outdoor photography, even from a private house, will be a breach of the agreement.
- L. E.—In the absence of any written arrangement as to a period of probation, there is no doubt that the retoucher is entitled to a week's salary and a further week's salary in lieu of notice.
- W. F. We have no knowledge as to the commercial manufacture of the range finder. Your best course would be to address an enquiry to the patentee, whose address was published along with the specification.
- G. A.—The mark on one of the prints is manifestly due to the spring, but we cannot understand why it should be there. We are using a single slide with a bright brass spring, but out of many hundred exposures not one has shown any mark. The only thing we can suggest, without seeing the slide, is to put a piece of black paper the size of the plate behind it.
- E. J. K.—1. Makers of focal-plane cameras in this country are Messrs. Houghtons, Ltd., 88/89, High Holborn, London, W.C.1; the Thornton-Pickard Manufacturing Company, Ltd., Altrincham; and Messrs. Ross, Ltd., 3, North Side, Clapham Common, London, S.W. 2. Most focal plane cameras are used by scale focussing only. As a rule the blind has an aperture the full size of the ground glass, and can be set open at this aperture to allow of focussing in the usual way.
- C. J. K.—There are half-a-dozen different models of printing boxes which are very suitable for running off from a dozen to 100 or 200 bromide cards. As we suppose, you would want to work by oil-light, about the best pattern is the Hana, made by Messrs. Houghtons, Ltd., 88-89, High Holborn, London, W.C.1. Most of the others are designed for use with electric light, although oil can be used by inserting a reflector. In the Hana, however, the negative is supported vertically; you thus get direct illumination when using an oil lamp.
- N. T. E. L.—The examples are very good, but, candidly, we do not think there is a market for the apparatus. The idea is a very old one, and from time to time attachments for the camera in the shape of a sliding shutter or a series of two shutters, fitted in some cases in front of the lens and in others a short distance in front of the plate, have been placed on the market. You will not be far wrong in assuming that the people who want to take these double and treble portraits are sufficiently interested in them to make the apparatus for themselves.
- W. J. A.—1. Yes, certainly you cannot do any dodging, except to a very limited extent by shading the negative. 2. There will be a little loss of sulphurous acid, but nothing material. 3. Increase

of hydrochloric acid causes decrease of density. 4. The granular appearance of the face is exaggerated grain of the paper in making the copy negative. You should not get this effect in direct portrait negatives, although you get something like it, due to the reproduction of the texture of the skin, when an ordinary plate is used. An orthochromatic plate used with a light-filter, such as a K2, will largely remove it.

F. W. H.—There is no firm which specialises in the transposition of stereo negatives, and none in the supply of requisites for stereoscopic work. The catalogues of Messrs. W. Butcher and Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.; or Messrs. Houghtons, Ltd., 88/89, High Holborn, London, W.C.2, show as full a range of stereoscopic goods as any other firms. As regards the cutting and transposition, the best advice we can give you is to apply to the secretary of the Stereoscopic Society, Mr. A. T. Mole, 39, Westbere Road, West Hampstead, N.W.2, who, we feel pretty sure, could recommend to you from among the members someone to whom you could safely entrust such work.

L. T. H.—One formula for this combined developer and fixer is as follows:—

Soda sulphite, cryst.	31 parts
Hypo	248 parts
Soda carbonate, cryst.	8 parts
Potass. bromide	8 parts
Water	800 parts
Hydroquinone	20 parts
Ammonia (sp. gr. .91)	45 parts

Another very similar one is:—

Water, to make	40 ozs. fluid
Hydroquinone	$\frac{1}{2}$ oz.
Soda sulphite	4 ozs.
Soda carbonate	4 ozs.
Hypo.	8 ozs.
Liq. ammonia .880	2 fl. ozs.

The plates are developed (and partly fixed at the same time) for two to three minutes, according to the temperature, and are then examined in daylight and fixed in plain hypo. More ammonia added to the developer gives more vigour, if required.

N. R.—When you exclude portrait photography you cut out what is the most professional branch of photography. When one comes to the others, they are frankly commercial, and therefore, perhaps—so we judge from your letter—not so likely to be congenial to you. Probably the most promising branch at the present time is that known as “commercial photography,” consisting of the photography of all kinds of articles of manufacture, engineering works, specimens in museums, paintings, and so on. It is a branch of work which needs a good technical training, but with a year at a school such as the Manchester College of Technology or the Photographic School of the Regent Street Polytechnic, you will get a good grounding, which would qualify you to begin business on your own in a small way, or to get a post as an assistant with a firm of commercial photographers. But, generally, the prospects of obtaining employment in photography are very uncertain. A great deal of new labour has come into the business during the war, and is likely to stay there, with the result that, as demobilisation has gone on, the labour supply has been considerably greater than the demand, and, we think, is likely to be for several years. If you have any real artistic ability and aptitude for portraiture, this latter is really the best branch which you can think of taking up, since you could start a small business with comparatively little capital, and with a reasonable chance of making a decent living.

R. S. (New Zealand).—We have no makers of soft-focus lenses in this country other than those of the portrait lenses of Cooke (Taylor, Taylor, and Hobson, Ltd.) and Dallmeyer, fitted with adjustments for soft focus, and the Bergheim lens. Even so, the portrait lenses give a comparatively moderate amount of diffusion of focus. All the lenses designed and sold specially for soft-focus effects are made in the United States. We give you the names of some makers taken from an “Almanac” of about ten years ago. Very likely there have been changes since then:—

Gundlach Manhattan Company (the Smith lens of about $f/6$),
Rochester, New York, U.S.A.

Spencer Lens Company, of Buffalo, U.S.A. (the Portland lens).

There was also the Pinkham and Smith Company, whose address we do not know, which was the first firm to sell a soft-focus lens, which was called the Smith. The only lens of this kind which we have used ourselves is the Verito, of the Wollensak Optical Co., Rochester, New York, U.S.A. It gives a very pleasing, but not excessive, diffusion at full aperture $f/4$, the diffusion being reduced as the lens is stopped down. The 7-in. lens, which covers a half-plate sufficiently well, although it is rather a short focus for this size, requires a flange of $2\frac{1}{2}$ inches internal diameter, $3\frac{1}{2}$ inches external diameter. The diameter of the lens hood is 2 inches and the over-all length of the lens from back to front is $2\frac{1}{2}$ inches.

L. C. M. (Sarawak).—1. In reply to your letter of June 25, which has just come to hand, nothing is better established in connection with the photographic portrait business in this country than that the photographer has the right to the custody of the negative. When a sitter comes to be photographed, and pays in the ordinary way, it is quite true, as you say, that the copyright in the portraits is the sitter's but the right of possession of the negative is the photographer's, and the negative is never handed over to the sitter except by special arrangement and payment of a substantial sum. This right (to the possession of the negative) has been confirmed over and over again in the law courts, and even in one case, heard in the High Court, in which a customer had to pay the photographer specially for certain negatives for the production of a special kind of photograph. In this case, also, it was held that the negatives remained in the photographer's possession. It is quite a mistake to suppose that sitters in England are able to get the negatives in order to have them printed elsewhere. We do not suppose that even special payment is made to obtain possession of the negative in one case out of ten thousand. This matter is fully dealt with in the handbook, “Photographic Copyright,” which we can send you post free price 1s. 2d. But in the meantime no doubt this statement will suffice for your purpose. 2. Charges for portraits range from four to five guineas per dozen down to, say, one pound per dozen. At the higher prices it is usual to take a number of positions, say, half-a-dozen, and to allow the sitter to select from these as he prefers in ordering copies at the dozen price. Charges for group photographs are very variable, but by good-class photographers about £1 10s. would be charged for taking a 10 by 12 group and supplying one print from the negative.

SUMMARY.

The first instalment of a contribution by Mr. Robert Dykes on night photography underlines the charm of this branch of work, suggests subjects, and proceeds to practical advice on apparatus. (P. 484.)

An article by Mr. G. Ardaseer gives succinct working instruction in photo-micrographic work without a microscope. (P. 423.)

Is there the intention on the part of the Photographic Section of the R.A.F. to waste public money by embarking on a programme of aero-photographic survey? We discuss the question in a leading article on p. 482.

Writing on the making of outdoor and garden portraits, in supplement to a recent contribution to the technique of at-home portraiture, Mr. Chas. H. Davis has some strong words of criticism of the "blur, fizzle, and falsity" which is passed off as art in this branch of photography. (P. 487.)

The storage—or, rather, filing—of negatives is the subject of this week's article by "Practicus," who describes the methods applicable to different classes of negative. (P. 489.)

Whole-plate, instead of cabinet, as the average minimum size of portrait, is a new policy being adopted by some studios, and is one which offers notable commercial advantages. (P. 482.)

Much sound judgment on the question of the selling prices of photographs is contained in a discussion of this subject by the *Photographic Journal of America*. (P. 490.)

The service of guide negatives and prints in securing a high uniform standard of output is the subject of a contribution to "Assistants' Notes." (P. 491.)

Some recent observations of ours in small towns suggest that business in certain styles of photograph is allowed to pass into other hands. (P. 481.)

View postcards, which should now come into popularity again, need to be benefited by a worthy process of reproduction and by more artistic quality and greater variety in the subjects themselves. (P. 482.)

In the making of photographs for use in advertising certain classes of goods there are evidences of a growing favour of diffused definition, coupled, it should be added, with genuine artistic qualities. (P. 481.)

Mr. Elwin Neame is introducing an invention of his own by which the photograph of any scene is utilised as the background for the sitter. Apparently the invention consists in the optical device for producing the combination negative at the single exposure on the sitter in the studio. (P. 482.)

Tint-laying, light edges in half tones, stripping in wet collodion are among the topics of "Photo-Mechanical Notes." (P. 491.)

An optical device for the division of light-pencils in duplicating the image of a lens is among the "Patents of the Week." (P. 492.)

EX CATHEDRA.

Sameness.

During a recent journey, we have been struck by the monotonous appearance of most of the photographers' showcases in several towns. The work has been in most cases of fairly good quality, but it has almost looked as if there was a "sealed pattern" for specimens. Almost invariably the mounts are brown, and the prints in black or sepia bromide. Little coloured work is shown, and that not of attractive quality. We have also noted the paucity of good enlargements on view. In one town we noticed a show of excellent work, but not including a single enlargement, while a few doors off a stationer was displaying several enlargements at a fair price, considering the very moderate quality. Miniatures either of good or cheap quality are also usually conspicuous by their absence, while stationers and cheap jewellers are pushing them as an accessory to the lockets or pendants they have for sale. It would look as if photographers had not yet learned how to get the best results out of their window displays, for we are sure that in many places it would be possible to add very considerably to their turnover by bringing forward something besides the cabinets and postcards which are shown to the almost total exclusion of other styles.

Soft-Focus Commercial Photographs.

The technical photograph which is made for the purpose of advertising articles of manufacture is so commonly required to be of sharp definition before anything else that a tendency on the part of advertisers to break away from this tradition may easily be overlooked. But the American advertising journal, "Printer's Ink," reminds us that among several large advertisers in the United States there is the deliberate policy to forsake photographic detail for breadth of effect, in other words to employ the soft-focus lens in making photographs which are still photographic in their drawing and tonal values, but get away from the hackneyed type of photographic illustration in their elimination of distracting detail. Clothing is one article which has been treated in this way. Instead of the photograph which makes the hand-drawn fashion-plate its model—on showing every stitch, button and fold—the policy has been to subordinate details to portraying an atmosphere of luxury. A leading advertiser of these goods is thus using a pronouncedly diffused photograph in which a man in evening dress is paying addresses to a well-dressed woman. The underlying suggestion is "that a man who wears this particular brand of clothes is entirely at home in these alluring surroundings, and he, too, may pay court to ladies fair and with a gallantry as to the manner born." The same idea is applied to other goods, to hats, pianos, cigarettes, to articles in short where taste and refinement of choice, rather than mere utilitarian motives, determine purchase. The point

of view is certainly one which must not be overlooked by photographers who cater for advertisers in competition with the artist-designer.

* * *

"Real Photo" Postcards. It is to be regretted that owing to war conditions the genuine bromide postcard views have almost disappeared from the shop-windows of stationers and others at the holiday resorts, and to a lesser extent from those in London. They are replaced by half-tone cards, usually of very inferior quality, even collotype appearing to be too costly in most cases. What is more deplorable is the influx of coloured litho, or three-colour cards of the coarsest type, which show a very decided lowering of the public standard of good taste. We trust that as we approach normal conditions again, we shall see the return of the bromide card, and to that end it is to be hoped that the producers of them will endeavour to raise the artistic as well as the technical standard. Many of the local views are poor in quality of negative, and uninteresting in subject. We need only refer to the views of the Hastings district, produced and issued by Mr. Fred Judge, to show that a very high artistic standard is a commercial proposition. Surely there must be many photographers who could produce really artistic views of their own neighbourhood, which they could easily get printed by the firms which specialise in this class of work.

Why Cabinets?

* * *

When the C.D.V. craze had reached its height, photographers were well pleased with the introduction of the cabinet portrait, as it enabled them, with little more labour and only a slight increase in cost, to produce pictures which could be sold for at least double the price obtained for the smaller ones. It would seem as if the time had come for a further step in size, and to our certain knowledge several high-class London photographers are making whole-plate prints their standard line, the receptionist being instructed to show nothing smaller unless it be specially asked for. There is much to be said in favour of this proceeding in localities where it can be introduced. Even at the present price of materials a very substantial increase in profits can be made by an advance of, say, 50 per cent. upon cabinet prices, and very often more than this percentage can be added. If the printing arrangements for bromide or gaslight papers are such that enlargements can be made as easily as contact prints, the plate bill need not be increased, and in the case of platinum and carbon orders the difference in cost between half and whole-plates is not worth considering, as adequate prices should always be obtained for these processes. As far as retouching is concerned, the cost of this for matt surface printing is probably less for whole-plates than it was for half-plate negatives for glossy paper.

The "Natural" Background.

* * *

According to a Sunday illustrated paper, Mr. Elwin Neame has devised, and is using, a system of taking portraits, the backgrounds in which are evidently produced in the negative from some scenic photograph which may be of any subject whatever. Thus, two examples of this process show Miss Ivy Close, barelegged and lightly clad, in one case striking an attitude in Bond Street, and in the other ankle-deep in a Manx stream. Such a method of combining the portrait of a sitter at the time of exposure with a background representing any selected scene has attracted inventors as long ago as about 1875, when a system of this kind was patented by Tilley. It was rediscovered in almost the identical form by a Swiss photographer named Dischner, and a somewhat similar device was patented a year or two later by a German of the name of Sontag. If

the brief newspaper reports are reliable, Mr. Neame's system must be different from the foregoing for he uses a camera of a size little short of that of a bathing machine in conjunction with artificial illumination of 80,000 c.p. For much of the combination photography which he produces for advertisement purposes such a process, we can understand, is exceedingly useful; but in the sphere of ordinary portraiture we are unable to see that it possesses any real advantages, unless novelty and sensation are counted as such.

THE PHOTOGRAPHIC SECTION OF THE ROYAL AIR FORCE.

It would appear that there is a desire on the part of those associated with the Photographic Section of the Royal Air Force to maintain that branch of the air service upon a considerable footing, and to do so by transforming in a large measure its activities from the military to the civil sphere. Only on such an assumption can we interpret the view expressed at a recent dinner of officers of the Photographic Section of the R.A.F. to the effect that it was hoped the British Air Ministry would appreciate the value of the science (of aerial photography) as soon as possible, and that every town, river, railway and road in this country should be photographed as soon as possible. Such is the opinion which we quoted in our last issue from a brief "Times" report of the social function. It is one which certainly calls for some examination.

Is it suggested that the Air Ministry has not accorded a full measure of recognition to aerial photography? Assuredly, the elaborate organisation of the Photographic Section, including a school of aerial photography at Farnborough, proves that it has—for military purposes. Moreover, the work of the Photographic Section could hardly have been more emphatically endorsed than it was by the military commanders, particularly during the latter period of the war. Press and public, as the result of the various war exhibitions, have also added a chorus of laudation extolling photography in the air, and ranking it high among the instruments of victory. Thus, the Photographic Section may surely be content: it has accomplished a great work with triumphant success, and, in the Service and out of it, has received corresponding recognition as the "eyes of the Army."

But perhaps it is not these now accomplished labours that are in the mind of the Photographic Section when appreciation of the value of the science is craved, but rather the further development of methods of aerial photography, of appliances therefor, and of new applications of aero-photographic methods in warfare. That is a very natural programme, but we cannot see that the suggestion to undertake a wholesale photographic survey of these islands from the air has anything to do with it. The disparity between the two things is so great that one is encouraged to think the association of the one with the other, or the suggestion of the latter as a development of the former, is simply the distortion of a very partial Press report. But as this is a matter which closely concerns those engaged in photography as well as the general public it is necessary to consider, with the object of arriving at a clear judgment of the matter, what are the possibilities involved.

In this connection the view of the Photographic Section seems to be that the war-created "science of aerial photography" should be further developed, and that the Air Ministry should also proceed to apply it to other than military purposes. On both of these propositions something requires to be said. We welcome the first if it means that, except for the now insignificant amount of aerial photography required in the field, the Photographic Section should resolve itself into an experimental depart-

ment equipped to study the mechanical, optical, and photographic requirements of aerial photography for the naval and military services. Such work as this has been done during the war largely on an emergency basis. Very largely, successive developments have been dictated by the circumstances of warfare, and very largely, too, the function of the Photographic Section has been to state its problems, and to leave their specific solution to manufacturers. A picked staff of a score or two under the direction of three or four heads familiar with the conditions of aerial photography, and in close touch with progress in flying and aerial warfare, would easily preserve the Photographic Section in a state of preparedness—a preparedness of ideas and solved problems—which hitherto in its short swiftly progressive history it has never been able to be in for long together. By adopting and forwarding such a policy as this, the Photographic Section will have the twofold satisfaction of gathering and fructifying the experience gained in the war, and of loyally contributing to the reduction of the wasteful expenditure from which the whole country is suffering.

When we consider the proposition that "every town, river, railway, and road in the country ought to be photographed from the air," we cannot avoid a misgiving that such counsels of prudence influence the mind of the Photographic Section. The suggestion implies expenditure in personnel and equipment of the order of that on a war footing, and whereas the work of aerial photography in France and other theatres of war had everything in its justification, there are several very good reasons why this peace programme should not be embarked upon by the R.A.F. until its urgent necessity has been demonstrated. In the first place, it has yet to be shown that aero-photographic survey of so well a surveyed country as England, or even of unsurveyed territory like parts of the African conti-

ment, is a sufficient substitute for the proved methods of the topographer, or requires to be used in supplement to these latter. Undoubtedly aero-photographic methods will come into use, and may prove extremely valuable, but they are still in the experimental stage, at which they call not for wholesale application, but for investigation and for comparison, as regards cost, speed and other features, with existing methods. At the present threshold stage of their development it is the easiest thing to carry out an immense amount of quite useless work. A further objection to the adoption of a scheme of this kind by the R.A.F. is that such civilian work is properly left to civilian persons and firms, to be done by them as circumstances show its commercial desirability. It is one of those enterprises that can very well wait for a year or two until its value is clearly established, and nothing is likely to be sacrificed by its elimination from the programme of a great Government spending department. We are prompted to lay more emphasis on this point than we otherwise should by the fact that in the many lists of surplus war material offered for sale by the Government we have hitherto seen no aerial photographic equipment, although we have reason to think that the stocks at the date of the armistice very largely exceeded the requirements of the Photographic Section on a peace basis. The fact may have little significance, or on the other hand, it may signify an attempt to direct the work of the Section into new channels. In view of the defective control over public expenditure at the present time it would perhaps be worth while to ascertain by a question in the House of Commons the number of personnel of all ranks in the Photographic Section now and at the date of the armistice, if recruits are still being admitted, if surplus material is to be disposed of, and if the work of the Section is to be confined in the future solely to photography in its application to warfare.

PHOTO-MICROGRAPHY WITHOUT A MICROSCOPE.

CONSIDERABLE interest was aroused by the show of photo-micrographic work held during February last at the Camera Club Gallery in John Street, Adelphi. The exhibition showed a few of the innumerable lines on which work by means of microscope and camera is being pursued. Incidentally, some of the remarks of the purely pictorial section of photographers, while not always complimentary, were at least amusing. From the catalogue it appears that the magnifications varied from $\times 7$ to $\times 3,000$ linear dimensions. Now, with low-power work—say, up to $\times 12$ —a microscope is not generally necessary, and any photographer who possesses a short-focus lens of about 3-inch focal length, and a camera with long extension, can set about doing quite successful work. The writer uses for such purposes a Voigtlander Collinear of 70 mm. focal length—say, 2.45 ins.—and with a triple extension half-plate camera of 23 ins. when fully racked out he gets a magnification of $\times 7$ without any additional extension device. The extensions are readily calculated from the formula $(M + 1) f = \text{distance between ground-glass screen and, for convenience, lens diaphragm}$, where M is the number of desired magnification and f the focal length of the lens.

Consequently for	$\times 4$	the extension should be	14"
"	$\times 5$	"	16½"
"	$\times 6$	"	19½"
"	$\times 7$	"	22½"

Of course, with a lens of shorter focal length, such as an Abbe 2 in., the magnifications will be greater with the same extension.

To rig up the apparatus it is best to have a base-board along the centre of one side of which a line is ruled lengthways. This simplifies centring the light and the object. The latter is held in some kind of holder, which will allow it to be adjusted to the axial line of the lens, and the illuminant is also adjusted to the same line. The diagram (Fig. 1) will

Fig. 1.

indicate what is meant. AB the baseboard, CD the camera, F a tubular extension to fit camera and take lens L, H the slide holder, shown in detail in Fig. 2, and I the illuminant.

Fig. 2.

The tubular extension used by the writer consists of a piece of a stout cardboard tube—originally that in which bromide paper was packed—about 6 ins. in length and 2½ ins. diameter,

and cut off accurately square; one end glued into a wooden camera front-piece and the other end fitted with a wooden disc with central hole to take the lens flange. It is important that the lens axis should be truly horizontal, and care must be taken to keep the disc end square with the tube. The object holder must have a hole about $1\frac{1}{2}$ in. cut, but with its centre exactly level with the height of the lens centre above the base board. The holder can be fastened to the base board, or its base may be weighted to give rigidity. The light—the writer uses an inverted incandescent mantle—slides upon a rod on a heavy square base. If runners are attached to the base board, between which the holder and light-standard can slide, matters are made easier in adjusting the illumination. The camera is clamped to the base-board, and the whole arrangement is such that the centre of the focussing screen, the centre of the lens, the hole in the holder, and the light are in one straight line. There is a small ledge, LL (Fig. 2), on the holder on which to rest the slide, and two curved pieces of watch spring, SS, are screwed on to it to maintain the slide in a vertical position.

A pencilled cross is marked on the ground-glass focussing screen at the intersection of its diagonals. The light is centred by focussing it on to the screen and moving it up or down or sideways until the image of the mantle is central with the cross. A piece of cardboard 3 ins. by 1 in., with a small hole in the centre, is placed in the holder, with this hole central to that in the holder, and the same focussing and adjustment of the holder is to be observed. The object—say, a section of wood—is placed in position, focussed first by racking out the front of the camera and a final sharp focussing—seen best through a focussing glass, set to give a sharp image of the pencilled cross on the ground glass—is effected by racking the back of the camera in or out until every detail is sharp. The light is cut off, preferably by interposing a piece of black card against the lens and between it and the object. The dark slide is in-

serted, the shutter withdrawn, sufficient time allowed to admit of all vibration ceasing, and then the card withdrawn and exposure made. The card is then replaced and the shutter closed. In many cases where the object is coloured a colour filter is almost a necessity, and a small holder for it, somewhat similar to the object holder, can easily be improvised. The filter should be placed close to the object (F in Fig. 1) and between it and the light. For mounted insects—generally of a yellowish colour—a K3 filter is very useful. The Wratten series of M filters, although intended for M panchromatic plates, are almost essential for successful results with other plates.

For opaque objects the light or lights are placed at the side of the camera, but behind the lens, so that no direct light falls into the lens, and sometimes a couple of lengths of magnesium ribbon burned one on each side will give excellent results. In fact, the procedure in this case is similar to that of copying. In a short article minute details cannot be entered upon, but there is one point, exposure, which is most important. Insufficient exposure is fatal to success, and the judicious waste of a few plates, in the sense of two or three strip exposures on one plate, will do much to give an idea of the correct time to expose. This, too, is governed to a large extent by the colour of the object, yellow, red, or brown objects requiring a very long time as compared with white, grey, or blue.

When focussing with the focussing glass it is very convenient to cement one or more microscope cover glasses with Canada balsam to the ground-glass side of the screen, and to focus the aerial image so produced. The writer, however, generally uses a focussing screen of his own make, as described by him in the "B.J." of June 27 last. He feels sure that any photographer who tries this method of low-power work will not stop there, but will desire to have a microscope as well, and wed it to the camera.

G. ARDASEER.

NIGHT PHOTOGRAPHY.

[Perhaps no branch of outdoor photography offers so great a degree of attractiveness as that of outdoor scenes under artificial illumination, particularly to those in large cities where an abundance of subjects of this kind is available. Since the immediately forthcoming season is the best time of year for night photography we take the opportunity of publishing a comprehensive practical article on the subject by an expert in it of long experience, Mr. Robert Dykes, F.R.P.S., formerly senior scientific assistant to the late Sir John Murray, K.C.B., F.R.S., and of the North Sea Fishery Investigations. Part of these notes appeared in a manual on night photography by Mr. Dykes, issued some years ago by Messrs. Dawbarn and Ward, but long out of print. In embodying them in his article Mr. Dykes has revised them, and has added one or two examples of his work, the reproductions of which on the paper and rate of production necessary for the "B.J." cannot, unfortunately, do anything like justice to the quality of the originals. In a succeeding instalment of this article Mr. Dykes will describe a method of introducing night and interior subjects into cinematograph films.—Ed. "B.J."]

EXPOSURES at night have now almost reached the snapshot stage, thanks to the rapid strides made in the production of fast colour-sensitive plates. What the future holds in store for us as regards quick exposures depends very much upon the skill of the lens and plate makers.

It is held by some photographers that night photography has few pictorial possibilities. To a certain extent this is so, for of the thousand-and-one subjects by day we have perhaps only one that may be suitable by night. Then, again, night work does not permit of the drastic treatment evidently meted out to some of the daylight productions seen at exhibitions. The lighting is so different, high-lights and shadow being much more difficult to handle. One cannot take this or that out and put something else in place very easily, because the slightest sign of faking is distinctly noticeable upon the negative. What one aims at in pure "nightscapes" is a clean, correctly exposed and properly developed negative, with the shadows

almost clear glass but full of detail, and the high-lights moderately dense, but free from any pronounced halation. Such a negative can be printed by contact, or enlarged, and, according to the process employed, the detail subdued if desirable.

Granted that night work has few pictorial possibilities, it yet has a charm all its own. Photographing in a large city at night, for it is largely city scapes we draw upon, we see it in quite a different light. What is a busy, noisy, uninteresting street during the day is now quiet, almost deserted, with fine clumps of heavy dark shadows emphasised here and there where a street lamp throws its reflection over the pavement. Think of Whistler striding around Chelsea after dark on a nocturnal prow, noting and memorising one of his beautiful nocturnes in black and gold. Who that has any feeling of romance or sense of the artistic would ignore the majestic and impressive grandeur of St. Paul's Cathedral looming up

out of the darkness as we walk up Ludgate Hill on a wet night, or the quiet of the Thames Embankment near Cleopatra's Needle on a foggy night, the stillness only broken by the hoots of river craft or of stray taxis. This is London wrapped in darkness as London or any city should be seen; for during the day, when its streets are throbbing with life and roaring with noise, the mind gets very little opportunity of appreciating the mystery and vastness of a great city. How many of us have often felt the desire to have a photographic record of some such scene? Or perhaps Trafalgar Square on a wet night, with its sparkling lights and brilliant reflections.

If darkness were absolute by night, photography might be out of the question except by flashlight, about which it is not

Stockholm from the Royal Palace. By Robert Dykes, F.R.P.S.

(This and other examples of Mr. Dykes's work in night photography are reproduced by courtesy of Mr. A. H. Pratt, of "Country Life.")

my intention to speak, but all the year round there is no time of the night perfectly dark from a photographic point of view. There is always a certain amount of light even out in the open country away from all apparent life, with no sign of an artificial light. I do not think that on the darkest of nights—once our eyes become accustomed to it—can we feel absolute blackness. The hedges and trees by the roadside loom up from the darkness of shadow to the darkness of an inky sky, yet they are discernible. Now, if the eye can discern objects at night, it is obvious that the more sensitive lens and photographic plate will do so, and at the same time pick up and record many things the eye could not see. If objects are discernible in the open country at night, how much more so must they be even on a very dark night in the city, where lights from thousands of different sources brighten the darkness and are reflected back from the clouds, giving a diffused light of great value for picking up detail in the shadows. Then, again, on a clear night, with a full or half-moon, we have a wealth of white light that is so highly actinic that even in December it is easy to over-expose and get a daylight effect.

Night photography is dependent, then, upon the amount of actinic light available at night, and this may be, roughly speaking, only 1/25,000 part of that obtainable at mid-day for an open city view. In other words, 1/25 of a second with $f/11$ would become fifteen minutes with the same stop at midnight. But the pictorial aspect of the work lies not in the direction of light, but in the proper handling of the shadows; it is the soft, mysterious, suggestive shadows, set off by a little light here and there, that appeal to the imagination. Night becomes a model which we may pose as our fancy pleases and our sense of poetic imagination allows. Shrouded in her wonderful shadow draperies, she becomes a dream of suggestion to the artistic mind, and, according to our mood, so may we portray our feelings. To take pictures at night does not necessarily mean taking photographic records of long processions of street

lamps. The great charm of pictorial night work lies in getting that Whistlerian atmosphere and breadth of effect, the correct rendering of large masses of shadow, with simple suggestion of line and subdued detail, and no pronounced glare of light; in fact, to endeavour to hit that soft charm and bewitching mystery that Whistler mastered, where detail was only apparent when you were not looking for it, and when you did it seemed to vanish into tonal masses of shadow.

The earliest exhibited night photograph was one of the Houses of Parliament at night, by Mr. W. M. Edmonds, in 1895, followed by Mr. Paul Martin in 1896 and 1897. Since that time some excellent work has been turned out by many workers in different parts of the world. Perhaps the most notable advance made in night photography was by Mr. Wild in his snap-shots reproduced in "Photography," in 1909, when, with an $f/3.3$ lens and panchromatic plates, he succeeded in taking night pictures with life at exposures of about a quarter of a second in the West End of London.

Street photography is perhaps the most fascinating form of night work. Little bits of street corners with a church steeple or a statue sharply silhouetted against the sky or some high-lights make very nice pictures. The exposure will vary from half an hour for a close view with few lights to fifteen minutes for an open view such as a large square, using $f/11$ and a rapid plate.

In wet weather the streets in places look their best; the lights scintillate bright and clear out of the darkness, and cast their reflections over the pavements. Under such conditions five minutes may be knocked off the above exposure.

Some churches when lighted up at night afford very pretty pictures, especially if the stained-glass windows are well illuminated. This class of subject is one for which I would recommend the use of rapid orthochromatic plates. With an aperture of $f/11$ give an exposure of thirty to forty minutes.

Myrdal in the Bergen Mountains. By Robert Dykes, F.R.P.S.

In most classes of night photography I much prefer ordinary rapid plates, as I have found that instead of orthochromatic plates being quicker at night they are, if anything, slower. Most of the lighting at night is yellow, and the shadows are very frequently blue. For this reason the ortho plate picks up and overcomes the high-lights before the shadows get a look in. In night photography we may consider that the high-lights are always considerably over-exposed and the shadows very much under-exposed. Then, again, they have to undergo such prolonged development that there is every risk of either chemical fog or light fog taking place.

Shuttering always lends itself to pictorial treatment, and on a fine clear night very good pictures may be obtained. Care must be taken to avoid movement either by rising or falling

tides, or by wind. The most imperceptible rock or sway of a ship's mast will spoil the photograph. Exposures are much the same as for street work—i.e., a rapid plate, well backed, $f/11$, fifteen minutes or so.

Some particularly beautiful skies are to be seen at night during the summer, and using $f/8$, a rapid plate, not necessarily backed, one can get a negative with three minutes' exposure, providing that the clouds are not moving too rapidly.

With a full bright moon exposures at night are not so lengthy, and an open view, such as a large city square, may be taken in six or seven minutes, using $f/11$ and a well backed rapid plate. An open view in the country free from artificial

Stockholm from the Katarina Hissin. By Robert Dykes, F.R.P.S.

lighting under similar circumstances will take half an hour to three-quarters. It is of no use attempting country work unless by moonlight, but bits of road with clumps of trees and perhaps a thatched cottage help to build up very pretty little views.

Care must be taken not to include the moon, or the result will be a long elliptical-shaped mark across the sky as a result of movement.

I may state with tolerable accuracy that all night photographs that include a moon are faked. The method of their production is to snapshot against the sun and to develop the negative up thin; artificial lights are then put in with the brush. Certainly these faked night pictures are very pretty, but they depend greatly upon cloud effects; and the artificial sources of illumination put in with the brush give a false and very feeble idea of light and shadow.

Mr. C. Heyl devised a means of including a real moon in the photograph simply by making an exposure on the moon and then capping the lens and waiting until it had moved out of the view, when the exposure was continued. Perhaps this is the best method of putting a moon into the view. I must warn intending "moonlighters" against over-exposure. One has a considerable amount of latitude in night work, but never give more than twenty minutes on a well-lighted street scene, with full moon, a rapid plate, and $f/11$. Five or ten minutes more than this, and no matter how carefully you develop your plate, the result is a *daylight* effect.

Illuminations, perhaps, are the first class of subject that tempts the amateur photographer to try his hand at night work. As with firework displays, the difficulty is to get a place free from the crowd. Illuminated buildings such as one sees at exhibitions make fairly good photographs, but there is too much symmetry, too much design, to make them really pictorial. A common mistake in photographing illuminations is to under-expose. One does not care to see simply rows

upon rows of fairy lamps with almost nothing to support them, not even fairies. Using a rapid plate, backed, and $f/11$, an exposure of at least twenty minutes should be given. Each little lamp is really not very actinic, and, taken individually, would not have much effect upon the photographic plate.

As regards apparatus, nothing special is required. Night photographs may be taken with the diminutive "Brownie," or the large 15 x 12 field camera. A great deal is to be said for the fixed-focus camera in this class of work, as it saves considerable trouble in focussing; but a full-sized view finder is necessary, otherwise an objectionable light that it is desired to cut out will in all probability be left in. In stand cameras the best form is undoubtedly a square bellows with an extensive rising front. If a conical bellows is used it must have loops to prevent cutting off the light. It is a decided advantage to have the lens carried on a panel, as it enables the front to be removed if necessary for stopping down after focussing when the f numbers cannot very well be seen. This panel should be easily removed, but quite firm when put in place again. A fine ground-glass screen is an absolute necessity in night photography, and a focussing magnifier cannot be dispensed with. Grease spots are of very little use for focussing, as one never knows exactly where the magnifier is likely to be applied on the screen.

What one really requires in night work, providing one has a camera and lens at all, is a rigid, steady tripod and the camera perfectly levelled, and last, but not least, a good stock of patience and confidence in one's self. You need it, especially in crowded places where the plaintive wail of "Please to take ma photy" or other choice remarks are hurled at you. If there is a strong wind blowing it is impossible to do anything, and it is better, if one cannot get a sheltered position, to abandon the attempt. I have walked six or seven miles to get a certain view, and then had to give it up owing to wind; so that even on the quietest of nights one must feel that the tripod is well

How a night negative should look when developed. By Robert Dykes, F.R.P.S.

set and free from vibrations. As to levelling, the levels should be placed where one can see them easily, no matter at what height they may be, and for that purpose there is nothing to beat Taylor, Taylor and Hobsons' single tube levels with the small side slit. I use one at the top of my swing-back for horizontal levelling, and one at the bottom placed at the side for vertical levelling. No matter how far above my head they may be, I can see the bubble cross the slit.

A light is essential. I use wax vestas, a piece of candle, or, if cycling, my cycle lamp; but to be absolutely "all there" as regards equipment an electric torch comes in very handy. Care should be taken in levelling, or distorted, intoxicated-looking lamp-posts or buildings will be the result.

"Flare" or "ghost images," through internal reflections in the lens, are in many cases caused by extraneous light entering the lens on the right or left from too closely adjacent lamps. To prevent this a lens-hood is useful. A cardboard box measuring about 4 inches deep by 6 inches wide, with a hole in the bottom sufficiently large to allow of its being slipped over the lens firmly in case of wind vibration, top outwards, answers the purpose admirably.

When working in wet weather or taking lightning flashes where there is a risk of getting the camera wet, a waterproof cover is necessary. Care must be taken to keep rain or mist off the front of the lens; it may be wiped, but *not smeared*, with a soft rag kept for that purpose, even during the exposure, providing precautions are taken not to move the camera in any way. On a cold night the lens should not be handled too much, or condensation of moisture may take place between the front and back combinations.

I have emphasised the importance of the camera being perfectly steady during exposure, therefore it is hardly necessary to warn photographers to avoid bridges where there is fear of vibration through traffic.

Coming now to the "eye" of the camera, for the camera without a lens is like the man without his sight. The better the lens, it may be supposed, the better the picture, but the cheapest of lenses nowadays gives remarkably fine photographs; and except for the fact that to obtain a sharp negative it is necessary to stop down and so increase the exposure, any lens will suffice.

Whatever may be the lens used, the aperture most suitable for work, in my opinion, is $f/11$, and in some cases even $f/16$.

so that with a lens having a full aperture of about $f/7$ we can increase the depth, make sure of our focus, and increase the sharpness of our high-lights by putting in a couple of stops. Of course, if it is possible to use an $f/3.5$ or $f/4.5$ lens and a panchromatic plate the lens need not be stopped down and exposures of seconds, or fractions of seconds, made that enable the picture-maker to obtain that suggestion of life which the man with an $f/8$ lens cannot get except by posing his life subjects.

The lights must have a little halation to give atmospheric effect, but too much is objectionable, and may be considerably prevented by stopping down unless very rapid exposures are being attempted.

Focussing should always be done with the full aperture of the lens and the stop adjusted afterwards. Artificial lights in the middle distance will generally be found the most convenient objects to focus upon, and these should appear as sharp-rayed stars and not simply as white circles free from rays. The effect of improperly focussed lights is to have a series of beautiful big black circles upon the negatives which print out about the size of half-crowns.

All exposures should be made with the cap, as it may be necessary to put it on and off during the exposure, and a shutter is not easily opened or shut without jarring the camera. Care should be taken to see that the lens is firmly fixed, and not likely to fall out of the camera front. Many of these remarks may sound absurd, but experience teaches fools, and the unexpected may happen even to the most cautious worker.

ROBERT DYKES, F.R.P.S.

(To be Continued.)

OUTDOOR AND GARDEN PORTRAITURE.

[In a further contribution to "The Photographic Journal of America," Mr. Charles H. Davis has set forth his views on his own practice of portraiture in gardens and other out-of-door surroundings. While the technical conditions are altogether different from those within sitters' homes, Mr. Davis is a firm believer in the commercial and artistic future of both branches of work. We commend what he now says to the notice of those who read his article which appeared last week.—Eds. "B.J."]

In making portraits in the open—in gardens or elsewhere—the photographer endowed with an artistic temperament and aspirations has the opportunity of his heart's desire. Practically every sort of a background, environment and lighting is possible. It requires only patience and the ability to see, select and record. The subject may be so placed as to get perfect relief, roundness, and good modelling, and added to these virtues we may produce delightful gradations of light and shade and delicate detail. These attributes of true pictorial portraiture are not to be lightly passed over as unessential, as some self-styled pictorialists would have us believe.

The marvellous possibilities of open air work are being demonstrated daily and nightly at the moving-picture exhibitions. They offer great opportunities for photographic study. For instance, in the charming presentation of "Rebecca of Sunnybrook Farm" there are many beautifully lighted scenes, in fact, unusual pictures may be constantly observed in the higher-class films. The magic of the *contre lumière*, and the shadow lighting, is made such a feature that one is constantly impressed with the beauty of this most flattering of all lights. It adds an ethereal quality and a poetic witchery that is always a delight to the eye and especially to the gentler sex. In recording light or blonde hair this style of lighting is almost imperative. The more brilliant the light the longer the exposure must be to get into the black shadows. Interesting sunshine lightings may also be observed and studied in the "movies." Time was when sunshine pictures were dead black-and-white; but the clever camera men have discovered the

right exposure and development, so that now there are few more beautiful effects to be seen than those made in the California sunshine, which seems unsurpassed for actinic quality and bright illumination. These odd and unusual effects that are never made in studios are the very things most sought after by appreciative people, and are not only more beautiful than commonplace lightings, but do much to render one's work distinctive, and tend decidedly to enhance the photographer's reputation. Such results are, moreover, delightfully picturesque, and place the successful makers quite in a class by themselves.

Much good out-of-door portraiture can be produced on overcast days. The sky is curtained by clouds, and locations are readily found in gardens or near buildings or walls, where the light from the sky on one side is unobstructed and the other side more subdued. This will give almost a skylight effect at times. Under the edge of a tree is a very successful place to work, and porches are quite ideal for head or figure poses. A spot near the end of the porch admitting light from two sides often gives a charming effect, and if a head picture is to be made the wall of the house—out of focus—makes an agreeable background. In gardens where there is a vista with somewhat distant trees we find most delightful arrangements. I make many pictures on dull days and with a certainty of success. Then all shadows are soft, and this condition is perfect for lined and wrinkled faces. These soft out-of-door lights obviate a great deal of the retouching sometimes demanded by sitters of this character.

Another very desirable spot for a portrait is alongside of a high hedge or shrubbery.

On the lawns surrounding country houses are to be found many large trees, the trunks of which form very attractive backgrounds. If a vista occurs at one side a pleasing composition of tree, figure, and vista is frequently possible. A group of two, apparently engaged in conversation, on a pathway, is another pleasing effect, always meeting with the approbation of the clients, and affording a picturesque arrangement with a suitable background. In fact, the possibilities of lawns with shrubs and trees and little vistas are almost limitless. A group on a bench under a large tree is easily managed, and can be most attractively lighted. All of these out-of-door arrangements may be made with very brief exposures, even on dull days, and they are a winning department of home portraiture.

When we look toward the sun or any brilliant light, we instinctively shade our eyes with the hand so that we may see clearly. For this reason a lens shade or hood is an indispensable part of a photographer's equipment. Light not coming from the picture area is not wanted in the lens; it produces fog, or semi-light-struck plates. Perfect definition and clarity of results cannot absolutely be attained without a hooded lens. The lens may be shaded by various makeshifts, and many times with disastrous results to the corners of the plate, but an adjustable hood is the most convenient and serviceable. I use one of my own construction, designed on the "lazy tongs" principle. It is made of strips of 1-16 in. x $\frac{1}{4}$ in. brass, riveted loosely at the joints, to permit freedom of movement in adjusting its length. The free legs at the back are curved to lie harmlessly against the camera, and the top is simply hooked on to the camera front. The whole contrivance is covered with black velvet and has a small set-screw for fastening the extension. In working against the light the hood is pulled out enough to cut off all top and side light up to the picture limit, and the degree of extension fastened with a set-screw.

Regarding pictorial photographs, I wish to say that the use of a soft-focus or diffusing lens will not in itself give a pictorial quality. This fact seems to be overlooked by many self-styled "pictorialists." The fundamentals of good composition, balance of light and shade, and lines of beauty must always constitute the agreeable attributes of any pleasing picture. All an imperfect lens can do is to suppress detail, and it must not be imagined in suppressing detail that pictorial quality is the automatic and inevitable result. On the contrary, the loss of detail frequently enables one to see more clearly how very little some "pictorialists" know about drawing and composition. The masses are made more solid by lack of detail, and often there is nothing to mitigate the bald imperfection of the result. Where hands are prominently shown on a near solid background of monotone, black or nearly so, the claw-like effect produced by the repetition of lines in the fingers becomes quite startling and repellent. Gracefully posed hands with changing and confluent lines in the fingers would be attractive in this treatment, but never otherwise. At the last Pittsburgh Salon I noted in particular a picture displaying these faults, and also another of an old lady with a cloak covering all but her head and three fingers of one hand. These fingers were without grace—just three stiff fingers, about as much alike as three bananas on their stem, and arranged much the same. The cloak showed a decided lack of lines of grace, and the face exhibited none of the attributes of good portraiture. As reproduced in the current periodicals the whole effect was smudgy, stiff and quite lacking a lovely pictorial quality. How can anyone think that such a result is pictorially interesting?

This brings me to another point: Why does the amateur believe, because he has a magical means of recording his work, that he can compete with artists who have spent years of study, under the guidance of acknowledged masters, before they venture to place their work on exhibition? Some of our self-styled pictorialists seem to think that they can jump full-fledged into the arena, and they actually do offer to the public, at exhibitions, all sorts of ill-considered efforts, and because they have used a soft-focus lens they serenely and triumphantly believe they are achieving masterpieces. Negatives are habitually undertimed and underdeveloped, yielding prints that have the slightest possible scale of gradations, some being in such a low key that they possess no lights whatever. These prints are in some cases so dark throughout that when under glass they mirror the features of the observer, instead of revealing an interesting work of art. This is a very poor substitute for a portrait of real pictorial photography. It is, in fact, pictorial piffle, and the authors might justly be called pictorial philanderers coquetting with art.

I am not decriing the use of soft-focus lenses or condemning novel or individual effects when they do not violate all the accepted canons of art. I am trying to impress upon the reader the necessity for more art knowledge, with the aid of which he may be able to produce artistic and genuine pictorial results. I have seen many charming, even beautiful, pictures made by the use of uncorrected lenses. I have seen better, however, made by the pinhole and by diffusion printing from sharp negatives. Every now and again, out of the fog and disappointment of blur and fizzle and falsity, emerges a real picture. I know from my own experience that these results may be achieved, but not regularly and with certainty. They are the result of a happy combination of fortuitous circumstances with everything working together for good. It needs skill and knowledge to produce pictures. I should say that the first essential would be the ability to make technically good negatives, with fully corrected lenses, embodying also good composition and irreproachable (or nearly so) drawing and lines. When this is achieved, the soft-focus variations may be begun with a certainty of occasionally producing beautiful results—provided always that wooziness is not overdone.

The pianist learns to play scales with freedom and faultless execution; this is, in fact, as everyone knows, the foundation of good piano technique. The photographer, likewise, must first of all, I assert, become a good technician before he can achieve interesting pictures. I grant you that technique is not interesting pictorially. It *must* be supplemented by other desirable essentials. Another thing: belonging to a mutual admiration society, such as some of the organisations seem to be, is not a certificate of pictorial prowess—it is, judging by the results shown, more of a demonstration of intrepidity. Some of the Salon pictures that have been awarded a place by kindred spirits prove this conclusively. Even at our professional conventions there is evidence of mutual aberration of the same kind. No matter where the fog leads there seem to be some who will venture to applaud and follow, though I am sure they could not give a satisfactory reason therefor. The futurist painter is a bug by himself. He sees red water, green skies and variegated people; but the properly made Autochrome shows no trace of these things in Nature. What a blow the Autochrome must be to such a painter! Let us beware of perverted photographic vision, and likewise let us endeavour to make good pictures that need no faking and apologies.

CHARLES H. DAVIS.

STOLEN SIBYL CAMERA.—Messrs. Newman and Guardia ask us to mention that a "Baby" roll-film Sibyl camera, No. 683, fitted with

f/4.5 Cooke lens, No. 66775, has been stolen from their premises, 17/18, Rathbone Place, London, W.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
 The Camera and the Lens (Jan. 10).
 Managing the Sitter (Jan. 17).
 Backgrounds (Jan. 24).
 Studio Exposures (Jan. 31).
 Artificial Lighting (Feb. 7).
 Printing Processes for Portraiture (Feb. 14).

 The Personal Factor (Aug. 15).

THE KEEPING OF NEGATIVES.

EXCEPT in some "while-you-wait" studios, where there is no pretence of preserving negatives, no business is too small to be able to dispense with a system of registering and storing negatives. The method adopted must necessarily be suited to the class of work done, that suitable for portraiture being different from that required for view negatives, and from that for commercial work. Two principal objects have to be borne in mind. The first is, the ready accessibility of any particular plate, and the second the protection of the film from deterioration.

I assume that everyone starts by giving the negatives a fair chance of permanency in the way of thorough fixing. If not, the most careful precautions will be unavailing. If a negative be imperfectly fixed, yellow patches will, after a time, appear where silver has been left on the film, while insufficient washing makes itself evident by a powdery appearance on the surface, sometimes even a fine crystallisation being present. In less aggravated cases the presence of a trace of hypo will cause a general yellowing of the image with a considerable loss of density. Even a perfectly fixed and washed negative is by no means permanent unless protected from damp and fumes, and there is no means of doing this effectively except by varnishing. When we remember that a silver coin or spoon will quickly tarnish in a town atmosphere we cannot expect the fine particles which form a photographic image to be less susceptible to change. This is forcibly illustrated by the uneven bloom which is often seen when negatives of various sizes have been roughly stacked together—say a quarter-plate next to a half-plate or other larger size—or where a negative has been treated with retouching medium in patches, the parts protected by the medium retain their original density and colour, while the rest of the image has become decidedly tarnished. It is therefore desirable to protect each negative by placing it in a bag or envelope, which not only keeps it from the atmosphere, but prevents scratching or rubbing during the necessary handling. There are two varieties of negative bag. One sort is made of thin manilla paper, and the other of a coarse transparent paper which allows of the subject being seen without removing the negative from its cover. I much prefer the manilla kind, as it is stronger, and also easier to write upon. The transparent ones are more easily torn both in inserting the negatives and in returning them to their positions

in the racks, and this I consider more than balances the slight advantage of transparency. The bags should be made with the smooth side of the paper on the *inside*—i.e., the reverse way of that adopted for ordinary letter envelopes.

The register number and sitter's name, which are, of course, already written upon the edge of the negative, are copied on to the bag, preferably at the top edge, so that it can easily be seen when turning over a number of negatives, while any notes or printing instructions may be written lower down, leaving a space of one inch between for the sake of clearness. In arranging the racks or shelves care must be taken to have them sufficiently strong, for closely packed negatives are very heavy in the mass, and will break down brackets or cleats which would support books or similar articles to the same bulk quite safely. The shelves should be made to give sufficient head-room to allow of a bunch of negatives being tilted upon one corner for the purpose of removal. Eight and a-half inches will be sufficient with half-plates, and the edges of the plates should not quite touch the wall or partition at the back of the shelf. This obviates risk of injury from damp and facilitates handling. As a general rule it is well to stack portrait negatives in the order of their register numbers, but not to mix different sizes in one rack. If the same order comprises, say cabinets and 12 x 10, a reference should be made upon the half-plate envelopes to the fact that missing numbers are to be found in the 12 x 10 rack, and a similar reference to the half-plates should be put upon the larger envelopes.

In some small businesses it is attempted to keep the negatives in ordinary plate boxes, with the customers' names outside. This is an inconvenient way, as a boxful has to be handled to find a single negative, and, moreover, when this system becomes outgrown every negative has to be numbered and an envelope provided and written. Even if there are only four or five thousand plates to handle this is rather a formidable job.

Publication negatives, either of views or portraits, are, in my opinion, best stored in card boxes, on the end of which is placed a label giving the necessary information as to the name of place or sitter and the negative numbers. With this class of work it is usual to be provided with a complete set of rough prints, either pasted in a book or kept in envelopes, each print being numbered. Having selected the desired subject, it is a simple matter to go to the rack where the boxes are arranged

in alphabetical order, and to take out "Love, Miss Mabel, 10,987," or "Dover Castle, 8,896," as the case may be. For negatives larger than half-plate I have found a system of vertical filing in boxes very useful. The negatives are put into bags, with a flap at one end about an inch wide. These are stood on end in a box just large enough to hold them conveniently. A sloping block or guide is put at the further end of the box, so that the negatives are slightly tilted away from the front. Names and numbers are written on the flaps of the bags, and these can be turned over like the leaves of a book till the required subject is reached. This is somewhat similar to Houghton's "Negasys" arrangement, but as some of my boxes go back to 1884 I cannot be accused of plagiarism. This system is also very suitable for film negatives, which are likely to be creased if stacked on shelves. Moreover, if the boxes are made of tin, with well-fitting lids, the risk of loss by fire is greatly reduced.

As it is difficult to insure valuable negatives for an adequate sum, it is a good plan to make transparencies of any special subjects, and to store these in another building, so that if the originals are burned or damaged by water it is easy to produce duplicate negatives, almost if not quite, equal in quality. One, at least, of the largest view publishing firms adopted this course with nearly all their subjects, and although I do not think they were ever called upon to use the whole series, the outlay was justified by the ease with which negatives, broken in the ordinary course of printing, could be replaced.

When it is impossible to duplicate a broken negative in this way it should be repaired as soon as possible before the broken edges have got chipped or damaged. I am no believer in the methods sometimes recommended of stripping films and transferring to new glass, or of cementing broken pieces together with Canada balsam, for the simple reason that few people have the skill to do it. In most cases it will be found sufficient to bind the broken parts on to a clean glass with passe-partout or lantern-slide binding, and to print upon a turntable. When large numbers are required the best plan is to make a transparency in this way, to retouch out all traces of the crack, and from that make a new negative. As an alternative a glossy bromide enlargement may be made, carefully spotted and copied in the usual way. Enlargements made for this purpose should be full of detail and rather flat as regards contrast. This can easily be obtained in the copying, and the heavy shadows so often seen in such copies will be absent.

It is a good plan, worthy of adoption by those who rely upon their rejected proofs for specimens to keep a classified index of suitable negatives, so that if it be desired to make a show, say, of children from one to two years old, the pick of the subjects in this class is available in a few minutes. This index must be kept up day by day as good subjects turn up, but the labour of doing this is very small compared with that of hunting through the negatives themselves.

Finally, the best system is useless if not properly followed out. A perfect filing system with, say, five hundred negatives not returned to their places is little better than no system at all.

PRACTICALS.

A DOVERCOURT CHANGE.—The photographic and art-dealing business of Mr. F. G. Steggle, of Dovercourt, has now been amalgamated with the large general and furnishing stores carried on by Messrs. J. A. Saunders, Ltd., of that town, of which business Mr. Steggle joins the board of directors, and, at the same time, remains in charge of the photographic department, which will still be carried on at No. 105, High Street, Dovercourt, where extensive alterations and improvements are being effected and a new studio being built, from the designs of Mr. Drinkwater Butt, F.R.P.S., the well-known photographic architect and photographer.

AS TO THE SELLING PRICES OF PORTRAIT PHOTOGRAPHS.

THE following is an American editorial view, that of the "Photographic Journal of America," on the question which lies at the root of every photographic business:—

What shall be the selling price of his photographs? is the most important question the professional is called upon to answer to-day. Various issues are raised, and so many considerations have to be met and settled that a right or wrong decision is vital in determining the success or non-success of a business. Should the prices fixed upon be too high, competitors will step in and seriously lower the demand for the higher-priced photograph; should they be too low, the status of the business will be reduced, the better class of customers bestowing their patronage on a rival. In both cases the business will suffer a falling-away of clients.

Whatever kind of work is done, there exists a close relationship between the *quality* of the photograph and the price it will command. The general public may not be expert judges of portraiture, of artistic merit, or technical finish, yet, by some means, they invariably form a correct estimate of the qualities of a photograph and the abilities of the photographer. The best work is always recognised as such; it secures a reputation and the consequent patronage. In most communities clients can be found who will support the man capable of giving them high-class productions, and are satisfied to pay good prices, simply for the name of the producer, as the hall-mark of superiority. Having this name, the photographer may almost fix his own prices, quite independent of what are the general rates in the locality. Once in possession of a name for superior work, it is essential that the reputation be sustained, and prices may then be fixed more on a knowledge of the social status of clients than in reference to the competition rate and the charges of other photographers. High-class portraits will always be sought after; they are obviously a luxury, and being comparatively rare they secure fancy prices; *they advertise themselves*, sitters are attracted from long distances, and the business ceases to be a purely local one. For these reasons, superfine work must always stand alone, the price being excessive, or, at least, very much in advance of the usual rates.

Beyond the field of work which depends for sale on quality alone, artistic taste, originality, and technical finish combined, there remains an opening for that which is supplied to meet a demand. There exists a permanent need for work of general excellence, supplied at rates that are not beyond the resources of intending purchasers, and hence the man who can meet this call at the lowest prices will secure the largest amount of patronage. Such prices are regulated entirely by competition of quality against price. If a locality is supplied by a photographer doing a certain quality of work, it will be useless for a competitor to ask higher prices for work of no better quality, or lower prices for work which is inferior. To attract custom, the portraits must be of better quality, supplied at the same or cheaper prices. To supply at a cheaper rate is, however, a mistaken policy, because it lowers the general rate; prices fall all around, and every photographer in the locality feels the effects—the competitor who commenced it in common with all others. To start a new business in a town hoping for custom on a reduction of prices is an error of judgment; it may succeed for a time, but, in the end, it must result in a general depression of prices. *The only way to successfully compete with others, and to keep a business together, is to improve the quality of work and raise the price.*

High prices are, in every instance, advantageous to the photographer. Photographs are, for business purposes, works of art; they cannot be classed with sugar or coal, as things people must have—necessaries, in short—and the price is not, like sugar or coal, fixed in the market to a large extent by the buyers. Skill enters largely into the production of photographs; it controls the price more than the cost of material or manufacture. The photographer has always to find a value for the skill he has displayed; if he puts this too low he degrades his status by under-valuing his abilities, and receives his profits, not on skill, but on cost of materials. By making skill the standard of value, the photographer receives his returns from that which yields the largest percentage of profit, and makes them independent of materials and cost of production, from which his profits can never be very large. In settling his prices,

the photographer must always take into account his training, the years he has spent in perfecting himself in his profession, rather than the bare cost of materials, etc., required in producing his work. Like the artist, he must charge for skill, and not merely to make a profit on the cost of paint and canvas. We thus see that the status of photographers controls greatly the prices of portraits; the higher the status of a photographer, the better able is he to demand, and obtain, a high price for his productions.

Beside this, he deals mainly with persons who are purchasing luxuries; the price paid by them will not interfere with or cause them to curtail their ordinary expenditure; hence, the photographer is dealing with clients who can afford to pay on a higher scale than could be expected for necessary articles. It is also generally overlooked that the photographer is not supplying a constant demand; his customers are mainly casual, and it is not to be supposed that a business of this nature can regulate its selling prices on the same lines as those which supply a daily or regular need.

The photographer who reckons the cost of material, wages, and indirect expenses, etc., and then allows over and above this a charge of 10 or 20 per cent. for profit, and puts his prices in agreement with the final figures, will soon find that it is impossible to carry on a business on these terms. Prices must be put to give quite 33 or 50 per cent. profit above cost of material, wages, and indirect expenses, otherwise a deficit will occur, arising from the fluctuating and casual nature of the trade in photographs. Even to deal in quantities at low rates does not yield a profitable return, because the market is not yet extensive enough. Millions of photographs must be supplied to make it pay, and such a demand is not yet reached. The intrinsic worth of a dozen portraits cannot be made the standard for regulating the selling price. The skill of the photographer, slack seasons, difficulty with help, advanced cost of materials, the fluctuating demand, the fact that the article is a luxury, and the first to feel a depression in trade—all these must be allowed for. From these various reasons, we conclude that the public are by no means overcharged for photographs, and that professionals would only be doing justice to themselves if present rates were advanced 25 per cent. all around.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Guide Negatives and Prints.

THE best and quickest method of judging a thing, and arriving at a conclusion regarding that particular thing, is by comparing it with something else.

Whether the subject be a railway train, a tube of pigment, or a photographic negative this holds good. Comparison with other trains, tubes, or negatives, as the case might be, would prove the most satisfactory way of judging the subject's worth, for merits and faults are more noticeable and more quickly noticed when seen relatively.

It is with abstract properties or qualities, though, that comparison plays the bigger part; the speed of a train, the brilliance of a pigment, the density of a negative are comparative, and without comparison they cannot be truly judged unless scientific operations and calculations be resorted to.

The busy practitioner has no time for physics, but he has time for comparison if he cares to provide himself with a standard to compare by. Take the case of negative development. It is usually assumed that the time and temperature tank system is safer and more productive of good results than any other, where quantities are concerned, and it is, when practised with scrupulous attention and on correctly exposed plates. But, alas! as most printers know, the scrupulous attention and the correct exposures are often absent.

I once saw a tank-room which had a set of negatives (let into a window) which could be illuminated at will. They were, in the proprietor's estimation, perfect negatives.

Anyway, they were the kind he paid wages for, and the develop-

ing operative was expected to keep up the standard, whether he relied on time and tank or not.

Having those negatives in front of him permanently he could never go far off the track; consequently, "bunged-ups" and "shadowgraphs" weren't known in that firm.

To come to what I call a "guide print." I found some years ago that the presence of a really good print in the developing room enabled one to work away all day in confidence that when seen in daylight the prints would not show a percentage of "too lights" and "too darks." Since then I have put this to a very decisive test, and believe that readers of the "B.J." will be interested, particularly those whose business includes the development of large quantities.

Noticing that the output of the developing room—some two to three thousand prints per day—was showing a relatively large number of prints which were not of an ideal depth, I distributed guides among the operatives, with instructions to gauge each print as near as possible by the guide. Immediately all waste on the score of too light or dark ceased. I thought this was proof enough, but a few weeks later it was strengthened considerably.

The old failing suddenly reappeared as bad as ever, and on investigating the matter I found the guide prints were "non est." As they had become familiar with them, the developing operatives thought it time to "just not bother," hence the prints of mixed depths.

The guides are each composed of two prints, both admittedly good when viewed in full daylight, one representing the most usual, and the other the next most common, styles encountered.

They were placed back to back, covered with two clean glasses, bound lantern-slide fashion, and the binding varnished.

In use they are left lying handy on the bench, preferably in the full light of the yellow lamp. A turn of the eye serves to show if a developing print is really as dark as it should be or not.

J. ROUSON HALL.

Photo-Mechanical Notes.

Laying Tints.

THE engraving department of a newspaper, or the shop doing much work for newspapers, will have no difficulty in laying tints, because it will have shading mediums and the proper apparatus for applying the tints. The house not engaged in doing newspaper work is seldom provided with this equipment, and yet occasionally a job comes in requiring a tint over some part of it, and the question arises as to the best way to do it. No doubt the best way is to pull a transfer on Scotch transfer paper from an engraved tint plate, which was the method in vogue before shading mediums were invented. This needs, however, some skill in inking-up such a plate, and requires a copper-plate proving press to get the best results, and it is more unlikely to find the plate, the skill required, or the press in the average photo-engraving shop than it is to find a shading medium equipment.

But almost any sort of tint-plate can be made in the same way that any other subject would be reproduced. If a simple stipple dot is required, a sheet of white blotting paper is put on the copying board and a negative made with the screen, and such an exposure as will give the size of dot desired. If a line is required, the same method can be adopted, taking the precaution to use a slit stop of the correct size and having the screen at the right distance. A very good line effect can then be produced. Etchings can be made from these negatives, transfers pulled, and applied to the plate to provide the tint in the usual way, and though the best transfers will be obtained from plates etched slightly in intaglio, as mentioned above, this requires the ability to ink up the plate and prove it in the copper-plate manner. Or, finally, the tint can be applied by the method of sur-printing. The subject is printed on the metal plate first, and developed, burned in slightly if the print is to be an enamel one, the plate is recoated and the tinted printed over, and rubbed away after development where it is not wanted.

Light-edge Against Dark in Half-tones.

A PHENOMENON familiar to the general photographer, particularly in tank development, namely the occurrence of a region of greater density adjacent to a portion of deep shadow also bothers the half-tone etcher. Negatives will be stripped to exact size and mounted together on a large glass, there being left between each negative a space of clear glass. Now the edges of the negative will frequently be sky or some other bright portion of the subject. When the plate is put into the mordant, especially when etching copper, face down in a still bath of perchloride of iron, the high-lights adjacent to the solids printed from the clear-glass spaces of the glass, will be attacked more rapidly and the dot sometimes etched away before the rest of the plate is nearly etched enough, and consequently the ink roller will dip there, giving a very disagreeable dirty effect where the plate should be brightest. The remedy is to give the mordant something to attack close to the light part, and the simplest way to do this is to take a piece of pointed stick and when the print is developed, and before enamelling, to rub away a little of the print from the black spaces in between, so that the acid will attack that part instead of exerting its entire strength on the edges of the picture next to these blacks.

Stripping Solutions for Wet Collodion.

THERE is some difference of opinion among operators as to whether the rubber solution and the stripping collodion should be thick or thin. There is no doubt, of course, that in the end one should have a film that is thick enough to handle without the risk of tearing, but if this is provided for, the thinner the solutions are, the more convenient to handle and the quicker to dry. The limiting factor for the rubber solution is that it must serve as an efficient insulator, to protect the collodion of the negative from being dissolved by the stripping collodion. If it does this satisfactorily, the thinner it is the easier to flow and the quicker to dry. If the stripping collodion is made from a suitable grade of cotton and has the proper amount of castor oil in it, it will be sufficiently flexible or "leathery" to answer every requirement, and again the thinner it is the easier to flow and the quicker to dry. Another advantage of thinner solutions for stripping is that the dangerous practice of lighting the coating to burn off the solvents in order to obtain rapid drying, can be prohibited, as it certainly should be. Some negative collodions are made from nitrated cotton that is so tough that with reasonable care they can be stripped without any rubber or collodion additional coatings, but most collodions are made from cotton that gives too fragile a film.

Using an Off-set Ink Image as a Negative.

A PATENT has been granted in the United States (No. 1,302,919) to J. A. H. Hatt, for a process of producing printing plates, which consists in preparing a sensitive coating on metal and then taking an impression on an offset roller from some design already prepared as a printing surface, transferring the impression on the sensitised plate, exposing to light, removing the ink image, developing, and then treating in the usual manner. The method is suggested especially for photo-lithography, and is to get more exact registration when several transfers are required in multicolour work than is probable in the usual way of making paper transfers. If positives are required from positives the first development will have to be reversed, as in the Vandyke process. One of the claims of the patentee is that by stretching or varying the tension of the offset surface before or after imprinting on it the design from the original printing surface, the size of the design on the final plate may be made either smaller or larger than the original design.

FORTHCOMING EXHIBITIONS.

September 13 to October 11.—London Salon of Photography. Entries close September 2. Hon. sec., 5a, Pall Mall East, London, W.C.1.

October 14 to November 29.—Royal Photographic Society. Entries close (carrier) September 19; (hand) September 20. Secretary, J. McIntosh, 35, Russell Square, London, W.C.1.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, August 5 to 9.

STEREOSCOPY.—No. 19,268. Stereoscopic cameras. A. L. Laurence and T. A. Locau.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each; post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

PRISM AND GRID FOR DIVIDING LIGHT PENCILS.—No. 127,308 (April 11, 1917). Fig 1 illustrates in diagram a photographic lens L and a sensitive film f , upon which it is proposed to form simultaneously at separated positions I, I' , like images of the object-field of the lens L . Such arrangement may be used for taking

Fig. 1.

motion pictures enabling the simultaneous taking of two pictures of the same scene from the same point of view on the same film.

Behind the lens are arranged prisms p^1, p^2 , having plane, totally reflecting surfaces T^1, T^2 , and meeting faces in the plane y inclined at an angle of 45° to the optical axis of the lens. A prism p^3 , having a totally reflecting surface T^3 , adjoins prism p^2 , and a parallel-faced transparent block p^4 adjoins the prism p^1 . The image beam from the lens L will have optically equal paths

Fig. 2.

Fig. 4.

from any point in the plane y to the image spaces I, I' , on the film f . The light-dividing means is located in the plane g to reflect part of the light through prism p^1 , and thence through block p^4 to the picture space I' on the film, and to transmit part of the light through prism p^2 , thence through prism p^3 to the picture space I on the film.

This light-dividing means consists of a grid G in the plane g . The grid G is characterised by irregularly shaped transmission areas r of a size separately perceptible to unaided vision, but so small as to occur in a relatively large number in the area of the grid normally included in the optical path. Reflection area or areas s occupy the remainder of the field. The total reflecting area (symbolised by A) bears a relation to the total transmission area (symbolised by R) which may be stated as $R=A/K$ where K is a constant expressing the numerical relation between the amount of light incident and the amount of light reflected by a continuous reflecting surface of the same kind as the reflecting areas. The values A and R may be varied as desired to vary

the intensity of the respective images. Thus, the total reflecting area may be enough larger than the total transmission area to compensate for the loss of light by reflection when images of equal intensity are to be formed.

The form and distribution of the respective reflecting and transmission areas are important to the result. The grid G, best

Fig. 3.

illustrated in Figs. 3 and 4, may be formed on a surface, for instance, of the prism p^1 , by coating the reflecting areas s with a dense bright deposit, such as silver. The Brashear or the Rochelle salts precipitating methods may be used. The deposit is removed or prevented from being formed at the parts r of the surface, thus providing unobstructed light-transmission areas.

The light-transmission areas r of the grid G are irregular polygonal figures having straight or irregularly curved joint boundaries oriented and scattered at random on the field. The remainder of the field is the reflecting area s . The object of this mutual arrangement of reflecting and transmission areas is to avoid any systematic or recurrent series of parallel boundaries between the reflection and transmission areas, which would result in cumulative diffraction spectra.

The cumulative disturbances caused by light-dividing surfaces having reflection and transmission areas bounded by parallel lines or other regularly recurring boundaries will be explained by reference to the diagrams of Fig. 5.

The diagram I (Fig. 5) illustrates the image of a narrow bright vertical line viewed through a series of narrow vertical openings, assumed to be transmission areas of a light-dividing surface. In

Fig. 5.

that case the image x in the direct line of vision is broadened by diffraction, as is well known, and on either side of the central image x dark and bright diffraction bands of different orders, a , a^1 , b , b^1 , etc., appear, being wider or narrower and more or less displaced from x as the narrow vertical openings are narrowed or widened; and brighter as they increase in number.

If the object is a bright point the appearance shown in diagram III results.

If the bright point is viewed through a round hole instead of a slit, a similar series of bands concentric with a central bright image is formed (not shown). If a number of parallel series of slits at angles to each other are used, additional diffraction spectra result of the kind shown in diagrams I or III. The amount of light diffracted away from the direct path depends upon the number of openings in the grid, and increases as they increase, while the distribution of this lost light depends upon the geometrical distribution of the edges between the transmission and reflection spaces. Any such systematic and cumulative diffraction figures are avoided by the form and distribution of the transmission and reflection areas of the grid G of the present inven-

tion, the diffraction effect of the many openings reducing to that of a single opening r .

For such uses as photography the broadening effect of diffraction caused by a single opening r is within the expected definition losses usual to the apparatus employed, such as halation in the sensitive coat of the film f , errors of lens surface, etc.

The effect of the grid G is illustrated conventionally in diagrams II and IV, Fig. 5. Diagram II illustrates, greatly magnified, the image at f , Fig. 1, of an artificial star, grid G being removed. Diagram IV shows the image of the star when the grid G is in place, similarly magnified.

The amount of the broadening of the image by diffraction caused by an opening r depends upon its size. The openings r must occur in the field of the lens with which they are used of such a size and in such frequency as not to form separate shadows. Referring to Fig. 6, if an obstruction s^1 is placed as shown, the point f^1 on the film f can receive no light from any part of the aperture of the lens L. If this obstruction is at s^2 , then part only of the source of illumination of the point f^1 is obscured. If,

Fig. 6.

now, there are a number of evenly distributed obstacles s^2 near the lens, the loss of light on film f is not local but general, and there is no local shadow on f . The reflectors s of the grid G are obstacles analogous to the screen s^2 in Fig. 6, and their permitted size is that at which they do not form separate shadows on the film f .

In practice, for a lens of $2\frac{1}{2}$ ins. (70 mm.) principal focus and 1 in. (25.4 mm.) aperture, a grid averaging 16 openings to the linear inch (6.3 openings to the linear centimetre) is recommended. The reflection area may be continuous or discontinuous, but it is recommended that it be continuous, as shown, to enable better retention on the prism surface.

For protection of the grid and to cause transmission of light striking the transmission surfaces at such angle that it would otherwise be reflected, the transmission surfaces are coated with an optical cement of greater density than the atmosphere, such as Canada balsam, filling the transmission openings r , and joining the two transparent prisms p^1 and p^2 , between which the grid is enclosed. Daniel Frost Comstock, 1,407, Beacon Street, Brookline, Mass., and Technicolor Motion Picture Corporation, Boston, Mass., U.S.A.

ROLL-FILM DEVELOPMENT MACHINE.—No. 126,814. (May 21, 1918.)

Apparatus for the daylight development of roll films or plates comprises a flexible collapsible tube open at one or both ends, the ends being adapted to be closed by folding and secured by a clamp or clamps. In the form shown in Fig. 3, the appliance comprises a thin rubber tube A in which the film roll 1 is placed and the open end of which is secured round the wrist by a glove-fastener 3. The film is then unwound and the free end secured by placing a clamp on the tube. The developing solution is poured into the open end of the tube beyond the clamp, which is then slightly loosened to allow the liquid to flow down the tube. The end of the tube is then folded over and secured by a clamp 5, which consists, as shown in Fig. 6, of two members, 7, 7a, pivoted at 8, and adapted to be held together at the other end by a pivoted U shaped catch 9. In a modification, Fig. 8, one or two spools 14 may be revolvably secured to a weighted carrier 11 and unwound into the tube by gravity. The empty spools may be removed if both ends of the developing tube are open. Plates may be developed whilst held in a metal plate-holder inserted within the tube, or the plates may be removed from the holder and the latter removed from the tube. In modifications, the tube may be formed wholly of flexible coloured transparent material such as celluloid, or may be formed with windows 16 of red celluloid as shown in Fig. 11. A gauge line or retaining

strips 17, Fig. 13, to determine the point of application of a clip, enable the closed lower end of a developing tube to be em

News and Notes.

REVERSAL IN FILM NEGATIVES.—Our contemporary, "Photo-Era," has drawn its readers' notice to the remarkable case of reversal in tank development of plates described in our issue of May 16 last by Mr. W. Bfins, and, as a result, has elicited details of a curious case of roll-film reversal from Mr. James C. Kerwin, a Boston photographic specialist. Our contemporary writes:—A six-exposure roll-film was developed with many others in a tank at a local photo-finisher's where Mr. Kerwin had charge of the developing room. When this roll of film was removed from the developing tank, exposures 1, 3, and 5 were negatives, and 2, 4, and 6 were positive. Two authorities in photographic physics were consulted, and, after a careful examination of the film, they came to the conclusion that this particular phenomenon was produced by carrying the camera about opened and with bellows extended. The owner of the film was questioned, and it was proved that the physicists were right with regard to the cause; but they could not determine positively the exact reaction that took place on the film. Briefly, the owner of the film visited a local point of interest on a bright sunny day. He opened the camera and made the first exposure. Then, with the camera still open and the film turned to the second exposure, he strolled about in the sunshine until he

made the second snapshot, after which he closed the camera. Later, he made exposure No. 3, and carried the camera exposed to the full glare of the sun with the film turned to exposure 4. It was exposed and the camera closed for the second time. Exposures 5 and 6 were made in a similar manner before the camera was laid aside for the day. The theory advanced was that a certain amount of light—imperceptible to the human eye—and the radiation of heat in and around the camera penetrated to the sensitive film and produced over-exposure, which, according to reliable authorities, is conducive to reversal. The first picture was an ordinary instantaneous exposure. The second was also; but before exposure No. 2 was made, the sensitive film had received the action of light and heat due to the camera being carried about exposed to the full glare of the sun. This same reasoning applied to exposures Nos. 4 and 6. Whether this theory is sound or not has not been decided. At all events, it is plausible, and should furnish a basis for others to work in the endeavour to account for the above-described phenomena.

Commercial & Legal Intelligence.

A PHOTOGRAPHERS' AFFAIRS.—At the London Bankruptcy Court last week the public examination was held of Harold Aylmer Jones, photographer, whose statement of affairs showed gross liabilities amounting to £367 4s. 9d. of which £288 17s. 9d. was due to unsecured creditors. To preferential creditors £78 7s. 0d. of which £77 10s. was expected to rank against the estate making the total liabilities amount to £366 7s. 9d. The assets consisted of cash at bankers 17s., but that was absorbed by the preferential claims, consequently the net assets were nil, and the deficiency was returned at £366 7s. 9d. The receiving order was made on November 13, 1918, on the petition of the creditor, the act of bankruptcy being the failure of the debtor to comply with the requirements of a bankruptcy notice.

In reply to questions put by Mr. Garton, official receiver, debtor stated that having previously been engaged as a photographer's assistant, he purchased for £28, a photographers business at 30, Hill Street, Richmond, in March 1916.

In March, 1918, he purchased for £100, of which £60 was borrowed, a similar business known as "The South Kensington Studios" at 7, Gloucester Terrace, S.W., which he conducted whilst his wife managed the Richmond business. The Gloucester Terrace business was not successful, and he was compelled to borrow money from professional money lenders, who obtained judgment against him, and in September, 1918, sold his goods at Gloucester Terrace under an execution. He then took a furnished studio at 64, Brixton Road, S.W., at a rental of 25s. per week, including the use of apparatus. He closed it, however, after a few weeks trading owing to lack of business. In July, 1918, he separated from his wife, and at the same time gave her the Richmond business which she was conducting at the date of the receiving order. He alleged his failure to have been caused through losses in connection with the business at 7, Gloucester Terrace, and to interest on borrowed money. He had produced the Richmond order book, but the books in connection with the Kensington business have been mutilated. There were no book debts due to him. The amounts he paid into his bank were less than the amounts he received in the business, but some of the monies received from the Richmond business were paid into the account of the Kensington business. In April, 1918, when he found the Kensington business was a failure, he became aware that he had not sufficient property to pay his debts in full. When he transferred the Richmond business to his wife, he did not owe her any money. The quarrel with his wife arose through jealousy. He had now become reconciled to his wife, and they were living together, but they were doing very little business. Owing to the fact that he did not attend for his public examination on the previous occasion, a warrant was issued for his arrest in April last, but he obtained a suspension of the warrant, by producing a doctor's certificate. He had been too ill to attend the Court, but had now presented himself because his health was better. He had never been bankrupt before or compounded with his creditors. The examination was ordered to be closed.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed or reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

AMIDOL.—Under Sect. 6 [2] the weekly half-holiday is resigned by the assistant in consideration of receiving a fortnight's holiday on full pay. We think the position in your case is that you can demand one or the other.

A. W.—We do not know what process is used for the purification of ox-gall, but you can buy the purified form, which has very little smell, almost none, from Messrs. Rheinlander and Son, Rodney Road, New Malden, Surrey.

J. F.—If your camera has an extension of 20 ins. you can copy-enclose from quarter-plate to cabinet with a lens of focal length as much as 10 ins. For convenience the focus should not be greater than 9 ins. Any shorter focus than this will of course serve equally well.

C. H.—You require to obtain a licence if you are now starting a studio, the Ministry of Labour having quite recently reversed its previous decision that a licence was not necessary. To obtain a licence you require to apply to the Secretary, Business Licences, New Arts Buildings, Liverpool.

W. J.—Your trouble is due to an excess of top light. You must cover up about half the light at the background end. Fix a fairly large reflector at one side so that it catches light from the roof to serve as a side light. You might even use a large looking glass, placed at one side at the camera end and tilted so as to light one side of the figure. A glass about 3ft. 6in. by 2ft. would do. We have seen this done very successfully.

J. K.—All the books you mention are numbers of the "Photo Miniature," and we doubt if any of them are in print. You had better try Messrs. Houghtons, Ltd., 88-89, High Holborn, London, W.C.1. If they cannot supply, then you may be able to get them direct from the American publishers, Messrs. Tennant and Ward, 103, Park Avenue, New York. The price of the "Photo Miniature" is now 1s. 6d. in this country, 35 cents in America.

D. E.—For a fixing bath of sulphite and hypo, good working proportions are 20 ounces hypo, 2 ounces soda sulphite, both by weight, to 8 ounces of water. The second formula you give is a very bad one, because both the alum and the citric acid decompose the hypo and make the bath milky. You had far better make up the bath according to one or other of the formulæ contained in the "Almanac." The first of these is a better formula than your hypo and sulphite.

W. S.—Your trouble is probably due to your lens having an excessively curved field. As you do not mention the type of lens, nor the size of plate you are working, it is difficult to give any definite advice. In the case of groups it is necessary with any lens to work with a smaller aperture than for a single figure. A good anastigmat or a portrait lens of adequate size should define a full-length cabinet at $f/6$ and a group of four at $f/11$, if the figures are placed fairly close to each other.

A. W.—As regards the uranium intensification, we cannot guess as to the red transparent patches, but the best thing you can do now is to put the negative in a weak bath of washing soda, wash well, then put it for a few minutes in a weak bath of acetic acid, say, 1 dram in 10 ozs. of water, and, after a further brief washing, re-intensify with uranium. Washing soda is a much better means of removing intensification than sulphocyanide, which is generally used very cautiously for taking out yellow stain in the whites.

J. H.—1. You can try what a weak solution of ammonium sulphocyanide will do to take out the stains, a cause of which very often is the use of the hypo-ferricyanide reducer on a print which has not been completely washed from a fairly saturated fixing bath. 2. There is nothing in the appearance of print No. 3 to suggest that white specks have been caused by prints rubbing against one another or through abrasion from other substances. In the specimen sent, the white specks are very slightly in evidence.

W. E.—Either of your schemes will answer very well, but we think that you are providing an unnecessarily large quantity of light. Few studios have more than six 1,000 c.p. lamps. Five 3,000 c.p. in a single box would give a very concentrated light, and require a lot of screening down—that is, if all were alight at once. We rather incline to having each lamp with a separate reflector and diffuser, and also a separate switch for each. Thin calico is a better diffuser than tracing cloth. We think that with this the curved bar arrangement would be most effective; of course, the bar would be on a swivel.

G. W.—If you make the backing simply with gum, water, pigment and caramel, it is bound to take some hours to dry. You want to make the mixture with a fair proportion of methylated spirit. Make your gum as strong as you can, and as syrupy; then dilute with methylated spirit so as to make a mixture which flows freely under the brush; also, there is a great difference in caramels as regards drying. The best caramel for your purpose is the kind sold specially for making backing by Messrs. Lichtenstein and Co., Chemical Works, London, E. You can buy small quantities from Messrs. Johnson and Sons, Cross Street, London, E.C.

J. R. H.—We do not know of a design of strip printer for amateur film negatives if you mean a machine for making the prints in a strip. Such an appliance, we should think, could be readily made an attachment to the film printing box of Mr. Marshall. We should doubt if a box of this kind is any quicker than the Kodak Quadruple Desk, assuming the user of both to be experienced. 1. The offices of the Ansco Co. in London are 143-149, Great Portland Street, W.1. 2. We believe Cyko papers are not now obtainable owing to import restrictions. 3. We have no reliable data, but, theoretically, the selenide should be more stable than the sulphide.

H. E.—There have been methods of toning three silver images, but the colours are very unsatisfactory, with the exception of the Prussian blue, very commonly used in three-colour synthesis. About the only yellow is one made by toning the image to one of lead chromate, but it is very opaque. Reds have been made by toning to mercuric iodide and other mercuric compounds. The failure of a whole lot of these processes arises from the opacity of these images. For three-colour work they do not compare with the use of a pigment or lake, as in the Raydex and carbon processes. Also, although we have not very fully considered it, we think you would have a great deal of difficulty in registering three transfers on each other.

J. S.—It is an uncommon problem, and one which we cannot recollect ever having been offered to us before. Generally, there is nothing in your procedure to account for it, and the only suggestion we can make is that the pinkiness of one print in fifty or so is due to the original black and white print not having been fully fixed before exposure to light in the hypo bath or immediately afterwards. Action of light at this stage, with a quantity of unaffected silver bromide in the emulsion, might conceivably leave a result which, while not appearing on development as a stain in the ordinary way, might show up as this slight pinkishness on sulphide toning. You must consider whether there is anything in this suggestion which corresponds with your practice.

H. W.—The address of the secretary of the Photographic Dealers' Association is Mr. A. Oglesby, c/o. Messrs. Sands, Hunter and Co., Bedford Street, Strand, W.C. There is a monthly paper for dealers—"The Photographic Dealer," Sicilian Avenue, Southampton Row, W.C. Trade terms to dealers range from within wide limits, according to the different classes of goods. At the present time your chief difficulty will be to obtain delivery of apparatus, such as small cameras saleable to amateurs. The trade is now very short of them, and at the present time a large part of the dealing trade is with second-hand apparatus. If we were you we should go very cautiously in spending any money just at present in establishing yourself as a dealer in new goods.

S. A.—1. In the British list of the Ansco Co., the buff Cyko paper is referred to also as "India tint stock," and it is this latter term which is used by the writer of the booklet on "Sketch Portraiture." We have no doubt the American house of Messrs. Ansco can supply this grade of the paper on your pointing out that you want the buff, either single or double weight. 2. Nigrosine is an aniline dye sold in two forms, one soluble in water and the other in alcohol, at a price here of about 1s. 4d. per ounce. No doubt you could get it, or its equivalent, from any of the dye houses in America. 3. The price of single issues of the "B.J." is 2d., or 3d. if posted to America. Numbers which are older than three months are charged double price—namely, 4d., 5d. post free to America.

H. H.—(1) We do not think it is the alum. It is more likely to be tiny air-bells on the print during fixing, preventing fixing from being complete. An after-bath of alum would make things worse if this is so, so you should try wiping the prints with cotton wool while in the fixer, and also use formaline 1 in 20 instead of the alum. If you do these two things we think the specks will no longer occur. (2) As a rule, no harm. (3) The fault is in mixing the starch. Use pure starch purchased from the chemists, and mix it first with only so little water that you can scarcely stir the mixture with a spoon or fork. Then pour on boiling water, and the paste will be as smooth as you can want it. (4) We do not see how the rubbing of cards can dirty the high-lights, but we are afraid we do not understand your question.

A. G.—(1) While prints are on the glass, a more or less waterproof backing paper is fixed on with thin, hot glue, or stiff dextrine paste, and the backed plates then allowed to dry. They can then be mounted without losing the glaze, or very often are simply trimmed down and used stiff as they are. (2) The white tank will make no difference whatever. (3) If the M.Q. developer intensifies, you are quite all right. Usually with this developer you have to redevelop in daylight, whereas with amidol you can dispense with daylight. (4) If the negatives to be printed are anything like some which you have sent us there is no artificial light except an arc lamp which is really satisfactory for rapid printing on gaslight paper. Your best plan is to fix up a printing box on your premises where it will get a north light, which will be fairly constant for the greater part of the day.

S. B.—We are unable to say which plates possess the highest gamma, but the reply which you quote was written from our knowledge of test exposures made some years ago by Dr. Mees and the late Mr. Welborne Piper at Messrs. Wratten's works. The kind of plate used was one like the Wratten Ordinary or Wratten Process Panchromatic, Imperial Ordinary, or Marion Academy Ordinary, in other words, a good liberally coated emulsion of approximately 100 to 150 H and D. With such a plate, in the case of under-exposures, it was found that the results by thorough development were actually better than with a plate of much greater speed, as indicated by the ordinary speed number. It needs to be emphasised that in the case of full exposures this effect of gamma does not come into prominence; it is only when you are giving an exposure which is perhaps only one-quarter or one-fifth of what you would like to give.

H. C.—We do not think that picking of the wood has been the cause of the dichroic fog. If the fog is really dichroic—that is, one colour by transmitted light and another by reflected light—

the most common cause is a minute quantity of a solvent of silver bromide (e.g., hypo) in the developer. It is quite conceivable that by using the same racks for fixing as well as for washing you may have introduced hypo into the developing tanks. We should give the existing racks and tanks a good soak in a solution of permanganate, making up a permanganate bath of fairly deep ruby colour, but not so strong but that it is fairly transparent in bulk of, say, 20 ozs. Repeat treatment of the racks and tanks with this permanganate solution until the colour ceases to be discharged. If the cause is hypo absorbed in the wood this treatment should remove it. Of the tanks on the market, as good a pattern as any is one of enamelled ware supplied by Messrs. Brodrick, Ltd., 50, High Street, Charing Cross Road, London, W. You could varnish the present tanks with any celluloid varnish, but any varnish is soon damaged in use, and thus exposes the wood of the tank to absorption of the solution.

C. G.—To explain the cause of your failure with the anaplanat would necessitate a long discourse on the subject of depth of focus in general, but it may be helpful to point out that the greater the focal length of a lens the less depth there is with any given aperture when working on a given subject, such as the room you mention. We find from a catalogue that the No. 5 Busch Pantaskop has a focal length of 10 ins., and the No. 5 rapid applanat having one of 18 ins., it would require a very small stop to give the needed definition throughout. As 10 ins. is not a short enough focal length to give a sufficiently wide angle on a 15 x 12 plate, the only thing to be done is to get a lens of shorter focus, such as the Dallmeyer wide-angle rectilinear or Ross wide-angle symmetrical, both of which have a focal length of 8½ ins. in the 15 x 12 size. The No. 4 Pantaskop might cover the 15 x 12, but we are not certain of this. Your best plan would be to apply to a dealer in second-hand apparatus and get some 8-in. or 8½-in. lenses on trial, telling them exactly what you want to do. It is a great help in taking such subjects to elevate the camera to 7 or 8 ft. from the floor and tilt it downwards until you get the view included, then set the back vertical. This will not only correct the perpendicular, but will bring the foreground into focus with a larger aperture than would otherwise be necessary. This plan is generally adopted when taking flashlight pictures of public dinners.

Line Advertisements. Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.

(No reduction for a series.)

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.

Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.

Displayed Adv'ts should reach the Publishers on Monday morning.
The insertion of an Advertisement in any definite issue cannot be guaranteed.

SUMMARY.

In the further instalment of his article on night photography Mr. Robert Dykes deals with the choice of plates and with the questions of exposure and development. (P. 501.)

In a second leading article reviewing the methods of making enlarged negatives we deal with those on the system of making a positive transparency the same size as the negative to be enlarged and producing from it the enlarged negative on plate, paper, or film. (P. 498.)

In his article this week "Practicus" deals with the chemical reduction of studio negatives, prescribing working instructions in the use of Farmer's reducer and in the employment of persulphate as a useful corrective of negatives which may suffer from the combined effect of slight under-exposure and over-development. (P. 499.)

A discussion of the various merits and demerits of the methods of preparing maps from aerial photographs is contained in a paper recently read before the Royal Geographical Society by Lieut.-Col. M. N. MacLeod, of the Royal Engineers. (P. 503.)

A letter from Mr. H. Hamshaw Thomas, an ex-officer of the Royal Air Force, takes up the question which we raised in reference to the future policy of the Photographic Section in our issue of last week. (P. 510.)

The essential features of cameras for aerial photography are described in two recent patent specifications. (P. 506.)

A contribution to "Assistants' Notes" deals with the fitting up of retouching desks particularly with a view to the comfort and convenience of the retoucher when employing artificial light. (P. 505.)

At a recent demonstration for the benefit of a Paris editor the photographic and photo-engraving staff of the "Daily Mail" prepared a half-tone block within thirty-four minutes of the original subject having been photographed on the Embankment. (P. 509.)

The death is announced of Mr. Henry A. Stroetz, a founder nearly forty years ago with Mr. George Eastman of the Eastman Dry Plate Company, which was the starting point of the subsequent enormous development of the Kodak enterprises. (P. 505.)

The present high price of silver, approximately 5s. per ounce, makes the recovery of photographic residues more than ordinarily remunerative. (P. 497.)

The suggestion of an attachment for the reflex camera similar in design to a trench periscope appears a cumbersome device for achieving the result which is readily obtainable in the ordinary use of a folding local-plane at the eye level. (P. 498.)

The large-aperture telephoto lens of the fixed-focus type is one which apparently is not rated at its full value by Press photographers, who, usually, are restricted to a camera of limited extension. (P. 498.)

EX CATHEDRA.

Residues.

If ever there was a time when it was worth while saving residues it is the present, when silver is about double the price it fetched a few years ago. Instructions for precipitating the silver from used-up fixing baths have been published so often that it is hardly necessary to reprint them. Moreover, most of the refiners are willing to give information upon the subject, Messrs. Johnson and Sons publishing a little booklet giving full details, and we believe furnishing suitable kegs for the purpose. In addition to the ordinary use of the bath it is a good plan to fix all waste bromide and P.O.P. as well as spoiled plates, so as to get all silver available into a form in which it can easily be dealt with. With metallic silver at five shillings per ounce it is worth while for those who are in only a moderate way of business to preserve their residues, while those in a large way should be doubly careful that nothing escapes the residue tub. Care must be taken to add sufficient potassa sulphurata to the hypo solution, but there should be no great excess. Moreover, the potassa sulphurata or "liver of sulphur" should be dissolved before adding, and not thrown in in lumps.

A Research Records Bureau.

At a recent conference convened by the Department of Scientific and Industrial Research, and attended by representatives of research associations, the proposal to establish a "records bureau" of the results of research was the subject of some usefully constructive discussion, in which Mr. Conrad Beck and Dr. R. E. Slade took part. It may be explained that the intention is to establish a bureau to take charge of the papers and other memoranda representing the work of individual research associations. The bureau will thus be a kind of clearing house through which research made for one industry will be accessible for the benefit of others. We are thoroughly in agreement with the policy of the Department to limit, at any rate for the present, the scope of the bureau to such records. If its files be open to a wide flood of technical literature, the bureau is bound to become proportionately inert; it will tend to become a museum, or even a mausoleum. The tendency of such bureaux is to give decent burial to documents deposited in them, but the determination of the Department is to resist the conception of its files as dead matter, but instead to extend their sphere of life by the Department's knowledge of the needs of each individual research body. This is an excellent policy, which should assure for the Records Bureau a total service higher than that of the far more comprehensive but less actively alive bibliographical institute, such, for example, as that at Brussels. Evidently it is to differ from these latter somewhat as a current technical periodical differs from the "Encyclopædia Britannica."

A Periscope for the Reflex. According to an American contemporary, an inventor has introduced a periscope—of the trench, not the naval, pattern—for the reflex camera, so that the Press photographer is thereby enabled to bring his view-point up to eye-level and save the situation for himself when the line of sight at waist-level is blocked. American Press photographers must be much more widely pledged to the use of a reflector camera than we imagine them to be if this cumbersome device finds any extended use. Here its suggestion merely signifies the disability of the reflex type of camera, which has led Press photographers to adopt almost exclusively the folding focal-plane instrument in preference to it. Lightness and portability apart, the folding focal-plane is the popular choice of the Pressman, largely for the reason of its effective use at the eye-level or higher, if need be, by holding it with the hands raised above the head. When this advantage is secured so easily there can be little inducement to attach a giraffe-like fitting to the reflex, nor to run the risks of cut-off and impaired definition on the plate which the twice-repeated reflection in the periscope involves.

* * *

Lenses for Press Work. For very good reasons the Press photographer, who has to focus by scale when using a lens with an aperture often as large as $f/4.5$, chooses one of as short a focal length as possible, but by so doing handicaps himself to a very great degree in the choice of subject, as many incidents which would make saleable pictures are in inaccessible positions for short-focus lenses. This is especially true of sports pictures, where the exigencies of the game, and the vigilance of the officials, keep the photographer at a distance. Obviously it is not practicable to use long-focus lenses of the ordinary type as the camera would be unwieldy, and there would be the necessity for carrying an extension body if the ordinary collapsible type of camera is adhered to, but by the adoption of the modern types of fixed focus tele-objectives it is an easy matter by simply changing the lens to get an image rather larger than twice linear from any given position as compared with the ordinary lens. In the early stages of telephotography much was anticipated from the telephoto lens, but as a rule the covering power at a magnification of two diameters was poor, and the definition not by any means sharp. With lenses made to work sharply at low magnification at such apertures as $F/6$, or even $f/4.5$, the circumstances are much more favourable.

* * *

The Import Restrictions. It is difficult to know exactly where we stand with regard to the importation of foreign goods. Apparently the elaborate consolidated list compiled by the Board of Trade, to which we referred in our issue of August 8 last, has now been completely knocked on the head by a memorandum issued by the Board of Trade on August 22 in supplement to the Prime Minister's sweeping statement in the House of Commons that restrictions on the importation of goods were to be removed. It now appears that these restrictions are preserved in the case of what are called "unstable key industries," the products of which are to be protected by the exclusion of like foreign articles. It is clear from the list of these key industries contained in the memorandum that certain products used in photography are thus protected, viz., sensitising dyes, synthetic photographic chemicals, and lenses. By "synthetic photographic chemicals" is presumably meant substances like developers. The list of the other substances which come in the same category agrees with this assumption. Pyrogallol acid is specifically mentioned in this list. The position with regard to other photographic requisites is by no means so clear.

"Scientific and optical instruments" is one of the key industries which is the subject of exclusion. The question thus arises whether cameras without lenses are "scientific instruments"; it is difficult to see how they can be "optical instruments." Evidently it will be necessary to wait for more definite decisions by the Board of Trade before this emergency and bureaucratic control of importation can be understood.

COMPARATIVE NOTES ON METHODS OF MAKING ENLARGED NEGATIVES.

II.

In the preceding article of August 15 we reviewed in a general way the methods which can be used for the making of enlarged negatives, and in particular those involving the making of an enlarged transparency. In the present notes we must come to the more commonly employed process in which a same-size positive transparency is made, usually by contact, and is enlarged to form the enlarged negative. The obvious advantages of this system are that it utilises the ordinary enlarging apparatus, it being just as simple to make an enlarged negative from the small positive as it is to produce the positive enlargement from a small negative. In comparison with the making of an enlarged transparency there is a somewhat lesser degree of facility in carrying out any retouching or other handwork on the negative, yet as a rule the small transparency allows of all that is necessary in this respect. If the system is less convenient and precise for the insertion of clouds into the enlarged negative the drawback may be thought to be more than counterbalanced by the extra labour of making the negative in the camera which the enlarged-transparency system involves. A good deal of discussion has ranged around the material which is most advisedly used for the making of the small transparency, the alternatives being carbon tissue or a dry-plate. For the former it can be maintained that the resulting enlarged negatives are necessarily better from the fact of the almost automatic reproduction of gradation in a carbon print as compared with the facility for variation from that gradation by errors in the exposure and development of a dry-plate. Advocates of the dry-plate, on the other hand, have emphasised its non-dependence on daylight and consequent greater speed in use. Without doubt, in the hands of the experienced, the one method will yield as good results as the other, and, again in the hands of the experienced, the dry-plate possesses a latitude which permits of effecting a considerable degree of improvement when making the transparency from a hard or a flat negative. On the other hand, with dry-plates it is difficult for the beginner to tell when he has made a transparency of the right kind. In this respect, presuming that the original small negatives are of good quality, the carbon process offers a much narrower field for mistakes than does the dry-plate, although it must not be forgotten that the carbon transparency, owing to its image existing in relief, requires more care in enlarging, and preferably should be illuminated by a system of perfectly diffused light such as daylight or a white reflecting surface instead of by the concentrated direct light of the ordinary condenser enlarging lantern. On the whole, it may be said that there is little to choose between the two alternatives when their individual facilities and drawbacks are considered.

When we come to consider the making of the enlarged negative, it is clear that choice will fall upon a dry-plate, bromide paper or Transferotype paper according to the particular requirements of the case. For the most straightforward enlarging and at the same time for the retention of the maximum "quality" of the original nega-

tive, a dry-plate of ordinary speed will be used; but, apart from other factors, among which is cost, the weight and fragility of enlarged negatives in any number offers a great inducement to replace the dry-plate by bromide paper. While most excellent enlarged negatives may be made in this way, it may be fairly said that their average quality is lower than that of negatives on plates, no doubt on account of the somewhat greater uncertainty of judging of the progress of development. On the other hand, the readiness with which both sides of paper negatives may be worked up with pencil or stump is a great point in their favour. The grain of the paper imposes the use of a matt or rougher medium for the prints, but that is a negligible item, since a matt-surface paper is likely to be used in any case. Oiling or varnishing of the paper negative has scarcely any discoverable effect in reducing this grain, and the maker of paper negatives may be recommended to forgo any "translucing" process altogether, for the comparatively small advantage in quicker printing on a print-out paper is certainly not worth the trouble and mess of rendering the paper more or less transparent. In this scheme of things Transferotype paper occupies a niche of its own in its facility of being handled like bromide paper until development, fixing, and washing are complete, and then of being transferable to glass for the production of a negative which differs in no way, except as regards a slight grain, from one made on a dry-plate.

A choice for the maker of enlarged negatives which

comes as a kind of intermediate between the processes employing an enlarged transparency and those using a small one is that in which an untuned and unfixed contact print is made on P.O.P., and photographed directly in a copying camera on to the large negative plate or bromide paper. This method, which is most expeditious in use, is one also which retains to an excellent degree the quality of the original negative. It can be understood that a P.O.P. print is a first-rate positive facsimile of the negative, and can be copy-enlarged in the camera by artificial light without suffering any flattening of its contrast by general light-action. If preferred, the P.O.P. print may, of course, be printed more deeply and toned and fixed in the customary manner, but there is actually no necessity for these additional operations. The process calls, of course, for a copying camera capable of taking a plate the size of the enlarged negative, and, therefore, perhaps is less likely to appeal to the ordinary amateur worker than is one in which a plate or paper of any size can be handled upon an enlarging easel. For professional use the process is one which deserves to be more generally used than, so we judge, it is. If our memory does not deceive us, it was this process which was placed first in the list of available methods, such as those we have outlined in these notes, for its results and convenience by Dr. D'Arcy Power, of San Francisco, in the course of making a series of comparative tests of the "quality" obtainable in enlarged negatives by the various methods available for their production.

PRACTICUS IN THE STUDIO.

{Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
 The Camera and the Lens (Jan. 10).
 Managing the Sitter (Jan. 17).
 Backgrounds (Jan. 24).
 Studio Exposures (Jan. 31).
 Artificial Lighting (Feb. 7).
 Printing Processes for Portraiture (Feb. 14).
 Studio Accessories and Furniture (Feb. 21).
 The Surroundings of the Studio (Feb. 28).
 Studio Heating and Ventilation (March 7).
 The Postcard Studio (March 14).
 The Printing-Room (March 21).
 About the Reception Room (March 28).
 Home Portraiture (April 4).
 Portable Studios (April 11).
 Copying (April 18).
 Handling the Studio Camera (April 25).

More About Lenses (May 2).
 Enlargements (May 9).
 Advertising the Studio (May 16).
 Mounts and Mounting (May 23).
 Business Methods (May 30).
 Photographing Children (June 6).
 Portraits of Elderly People (June 13).
 Something about Lenses (June 20).
 Hand Cameras for Professionals (June 27).
 The Dark-Room and Its Fittings (July 4).
 Plates and Their Work (July 11).
 Apparatus Repairs and Renovations (July 18).
 Posing the Head (July 25).
 Intensifying Portrait Negatives (Aug. 1).
 Workshop Jobs (August 8).
 The Personal Factor (Aug. 15).
 The Keeping of Negatives (Aug. 22).

THE REDUCTION OF NEGATIVES AND PRINTS.

ALTHOUGH almost as necessary a process as intensification, the reduction of photographic images, either negative or positive, is not usually carried out with equal success, even the simplest methods being regarded as risky by many operators. There is no good reason for this idea, for with ordinary care there is no danger either of destroying the image or staining the film.

Nearly all non-mechanical methods of reduction consist in converting a portion of the metallic silver image into a soluble salt which can be removed by a "fixing" agent such as cyanide of potassium or more commonly hypo, the outstanding exception being the persulphate method, in which a silver salt soluble in water is formed.

The process of reduction, like that of intensification, may be carried out in either one or two stages, the latter being the

earlier form, the soluble salt being formed by immersion of the negative in one solution while the removal was effected in another. As examples of this, I may give a preliminary bath of perchloride of iron or of diluted tincture of iodine followed by a plain solution of hyposulphite of soda. This procedure was effective in its way, but had the disadvantage of not being under control, as it was difficult to judge of the amount of reduction until the negative was removed from the hypo bath. It was therefore a great advance when Mr. Howard Farmer introduced the ferricyanide and hypo reducer, in which the conversion of the silver into a soluble form and its solution took place simultaneously, thereby permitting any desired degree of reduction to be obtained.

It should be noted that in the case of nearly all reducing

solutions the degree of concentration has a marked effect upon the result, a strong solution dissolving the more delicate half-tones away entirely before any perceptible effect is made upon the high-lights, while a weak solution has a more even effect all over the image. This may be taken advantage of, as it allows of fog being quickly removed by a strong solution if it be desired to do so before intensification.

Most of the troubles which occur in reduction may be avoided if ordinary care be exercised in preparing and using the solutions, and I therefore give clear instructions which, if followed, will help to avoid stains and uneven action.

The ferricyanide and hypo or Farmer's reducer is the most generally useful, as its action is easily controlled, and there is no difficulty in its preparation. Where it is in constant use the best plan is to have two stock bottles, one containing a plain hypo solution containing three ounces of hypo to the pint, and the other a 10 per cent. solution of potass ferricyanide. These are mixed for use in such proportions as may be needed, the colour being a good guide. Thus, if we take, say, two ounces of hypo solution and add to this enough ferricyanide solution to give a pale lemon yellow, the action will be slow, but even—that is to say, that the high-lights will be reduced in the same proportion as the shadow details or any fog which may be upon the deep shadows. A large proportion of ferricyanide, giving a deep golden yellow, acts very quickly and will clear fog off the deep shadows of a negative before it has time to penetrate into the film sufficiently to affect the image to any appreciable extent. This property is very useful when dealing with over-exposed and over-developed negatives, such as are occasionally met with in tank development. It is a good plan, and economical of chemicals, to apply the strong solution with a swab of cotton wool, of course keeping the latter in constant motion. This also allows of a little local action, so that a white skirt or bodice may be reduced without unduly affecting the face, hands, or other draperies.

There are a few precautions which must be taken to make sure of clean working. The hypo solution must be clean and fresh, and an acid fixing bath must not be used. A weak hypo solution must not be used, as this tends to give yellow stains. I have seen it recommended in some text-books to take a couple of ounces of water, to add to this a few drops of fixing bath and a few drops of ferricyanide solution to make the reducer. Such a proceeding leads to an unjust condemnation of the method as useless. The mixed solutions must not be used in a strong light, as the ferricyanide is rapidly decomposed, the solution first bleaching and then turning a pale blue. Some workers prefer to dissolve the crystals of ferricyanide directly in the hypo solution. This is equally effective with using a 10-per cent. solution, but is a little more trouble, as the mixed reducer will only keep active for a very short time.

If through disregard of the foregoing precautions yellow stains occur, they may generally be removed either by the iodine and cyanide reducer or by a weak solution of potassium cyanide.

While the "Farmer" reducer tends to give increased contrast, the persulphate reducer has an opposite tendency, and will so alter the character of a harsh under-exposed and over-developed negative that quite soft prints may be obtained. It is very simple in action, but, curiously enough, I have found more people make a mess of its use than almost any other process in negative-making. Flat over-exposed negatives are not suitable for this method, no matter how dense they may be. The type that it is especially useful is a sitter in dark clothes, where there has been considerable under-

exposure, and the hands and face over-developed in an attempt to secure detail in the shadows.

We require two solutions, both of which should be freshly made. One is ten grains of ammonium persulphate to each ounce of water. This I usually mix in the dish immediately before use. The other is a 5-per cent. or, even better, a 10-per cent. solution of sodium sulphite, which is kept in a dish ready for immediate use. The negative must be perfectly free from hypo, and should be well soaked in water before reducing it if it has been allowed to dry after fixing and washing. It is then immersed in the persulphate solution. The action may commence at once, or it may be ten minutes before any action is visible, which, if the solution be made with tap water, is manifested by a milky appearance. As soon as this is noticed the negative must be constantly watched, as reduction then proceeds rapidly, and it is easy to overdo it. As soon as the desired point is reached the negative is quickly rinsed under the tap and transferred to the sulphite solution, in which it should remain at least ten minutes, after which it should be well washed.

Some samples of persulphate will not attack the image at all until slightly acidified. If no action is visible after ten minutes' immersion, remove the negative from the solution and drop in a very small quantity of dilute sulphuric acid (one part acid to nine parts water). Ten minims of this is ample for two ounces of the persulphate solution. If too much be added, the action will be very rapid and uneven, the image going to a pinkish ghost before the action can be stopped. If the negative has been handled with fingers contaminated with hypo, any portions which have been touched will refuse to reduce or, at all events, hang back behind the clean portions.

A very clean and useful reducer is that composed of iodine and cyanide of potassium. The action of this is very similar to that of the "Farmer" reducer, but as it is extremely poisonous, it is not so generally used. I have, however, found it so useful upon stained negatives and prints that I give details of its preparation and use for those who are careful not to leave cyanide about loose. This caution may seem superfluous, but when I say that I have seen a girl using a 5-per cent. solution of cyanide from an ordinary teacup which a few minutes before had been used for its legitimate purpose, it is not so in all cases.

Two stock solutions which will keep indefinitely are made thus:—

A.—Potass iodide	150 grs.
Water	2 drachms
Iodine (in flakes)	45 grs.
(Stir till dissolved and make up to 1 oz. with water.)	
B.—Potass cyanide	1 oz.
Water to	10 ozs.

For use, take for average work 30 minims of A. and 5 minims of B. to each ounce of solution. It may be used much stronger or weaker, to suit special cases. I have found this reducer very useful for cleaning green fog off negatives, and also for removing the muddy appearance caused by the forced development of bromide prints. I prefer this reducer before all others for lantern slides or other transparencies, as it does not alter the colour of the image in the slightest degree.

Both this reducer and the ferricyanide and hypo are suitable for bromide and gas-light prints, but I have not found it desirable to immerse the prints in the solution. A better way is to lay the print on a glass plate or the bottom of an inverted porcelain dish and to swab the solution over with cotton wool, occasionally rinsing under the tap. Stained margins may be cleaned and faulty vignettes corrected very easily.

There is another way of using iodine for reducing bromides which may be referred to, as it affords a means of brightening up a flat print. It is to take, say, a drachm of the iodine solution (A.) in ten ounces of water and to immerse the print until the high-lights begin to turn blue. The back of the paper quickly turns blue, but no notice must be taken of this. The print is then rinsed and transferred to a plain hypo bath (3 ozs. to the pint), in which it should be left for five minutes. If the reduction is insufficient, the process may be repeated,

taking care to wash out all traces of hypo thoroughly beforehand.

I have found no really satisfactory way of reducing P.O.P. prints without altering their colour. On the whole, a very weak solution of cyanide seems the most satisfactory. A drachm of 10-per-cent. solution in a quart of water is quite strong enough, and with some papers this might be diluted to one-half strength. The reduction should take place slowly or the half-tones will entirely disappear.

PRACTICES.

NIGHT PHOTOGRAPHY.

[Perhaps no branch of outdoor photography offers so great a degree of attractiveness as that of outdoor scenes under artificial illumination, particularly to those in large cities where an abundance of subjects of this kind is available. Since the immediately forthcoming season is the best time of year for night photography we take the opportunity of publishing a comprehensive practical article on the subject by an expert in it of long experience, Mr. Robert Dykes, F.R.P.S., formerly senior scientific assistant to the late Sir John Murray, K.C.B., F.R.S., and of the North Sea Fishery Investigations. Part of these notes appeared in a manual on night photography by Mr. Dykes, issued some years ago by Messrs. Dawbarn and Ward, but long out of print. In the final instalment of this article Mr. Dykes describes a method of introducing night and interior subjects into cinematograph films.—Ed. "B.J."]

(Continued from page 487.)

COMING now to the question of plates and films. Any plate or film may be used, no matter how quick or how slow, only as we do not care to stay out all night over an exposure—the quicker the plate the better. I have seen it stated that it is immaterial what speed of plate you use at night; that a slow plate, given the same exposure as a rapid one, will give identical results. Now, as far as my experience goes, this is incorrect, as I know to my cost. My advice—and it is based upon over one hundred experiments with different plates—is use the quickest plate obtainable. We have a large selection to choose from, and it is quite unnecessary for me to enumerate the many different varieties all equally good. Perhaps one of the best for its rapidity, close grain, and clean working, is the Ilford "Monarch" backed. I use a great many of them.

Backing plates is a somewhat troublesome and messy proceeding, but a very necessary one in night photography. It is preferable to purchase one's plates already backed and to give them an additional coat when used against a wealth of artificial light, such as exposures in railway stations. As a rule, the plate-makers put on the backing in a highly uniform manner, but the plates should be examined before use to see that there is no streakiness or brush markings. The marks develop up very frequently, causing peculiar aurora borealis effects; this is a common complaint in backing plates oneself unless care be taken. Mawson's "Antalo" is very handy for putting on an extra coat. To apply it, lay the plate emulsion side down on a pad of red blotting-paper, shake up the bottle thoroughly, and pour about ten drops or so upon the centre of the plate and spread it carefully over the whole surface with a soft camel-hair mop. Badger's hair or other forms of brushes are too hard, and tend to cause streaks. After a few moments the plate will be sufficiently dry for use. All this work must be done in the dark room with a perfectly safe light.

The object in backing plates is to prevent halation due to high-lights such as electric arc lamps, but no amount of backing will entirely prevent it; and although too much is a decided fault, a little is indispensable to give atmospheric and pictorial effect.

Double-coated plates such as the "Seed" dispense with the need for backing. They are almost entirely free from halation, and should most certainly be used if it is intended to make lantern slides of the views taken. The high-lights stand out crisp and clear, and are free from "circles," "flares," and radiating rays, the latter due to either streaky backing or to

halation. Some extraordinary effects of halation have been obtained by the writer due to using unbacked plates and bad choice of position for lighting. In many cases the rays from the high-lights terminated with peculiar knobs, so that one had a street lamp with rays radiating outwards from the centre, and each ray like a rod with a knob on the end of it. Again, it was a common occurrence to have around each street lamp or other high-light a series of rings from the centre outwards: first, the white centre light, then a dark circle, and then another white circle or halo. These peculiar effects, of course, are characteristic of extreme forms of halation.

Rapid ortho- or panchromatic plates are excellent for certain classes of night photography, but there is considerable risk of light-fog and chemical-fog in development, especially if the development is prolonged to obtain detail in the shadows. If used against a wealth of light, with a quick lens at $f/3.5$, and at an exposure of about one-fifth of a second, there is practically no time for serious over-exposure on the high-lights and consequent halation, and the shadows will yield what detail they have by fairly rapid development, i.e., ten to twenty minutes.

Before attempting to give some idea of exposure and the method of development, I may with advantage offer a little advice as to prospecting for likely views, and some of the things to avoid. In choosing a point of view, certain little things should not be overlooked. In the first place, the nearest and brightest light, whether it is objectionable, and if so, how to avoid it. The best time for taking the view must be considered; if too late at night a large amount of the light required to build up the picture may be off, owing to shops shutting, etc. Then, if too early in the evening, there may be a great many moving lights, or, what is worse, a cab rank, and cab ranks are a rank nuisance at night from a photographic point of view. Or perhaps one may be photographing in a park when it is about to close, and the camera must perforce close also, and you clear out. The lights of bicycles, or any forms of vehicular traffic should be kept out of the lens, no matter how rapidly they may be moving, or the plate will be crossed by innumerable black lines, that on printing will look like scratches, clothes lines, or telegraph wires.

To the novice, the question of exposure by day or by night is a vexed one, and, judging by the look of some daylight productions, they might at first be considered as night effects, until you are informed that this or that view was taken in the middle of the day or late in the afternoon, with an exposure of about 1-1,000 of a second, or even less. An actinometer can-

not be used at night, and only experience will teach the correct exposure. In exposing, a little on the over side is better than on the under, as it is easily remedied in the dark room, and it is exceedingly annoying to find nothing on the plate after a long tramp and half an hour spent in development, all through under-exposure. If the sky be particularly dark there is not much risk of over-exposure; it is when illuminated by a full moon or on a summer night, when distinctly blue, that one runs the risk. There is an old saying amongst photographers with regard to daylight work, viz., "expose for the shadows, and let the high-lights take care of themselves." Well, this is equally applicable to night work. Get all the details possible out of the shadows, and the worst that can happen is the reversal of the *centre portions* of high lights, such as arc lamps. It is a comparatively simple matter to put this right with a brush. Strictly speaking, a properly developed night negative is under developed in the high-lights, and fully developed in the shadows.

I have prepared a table of exposures which may be of some assistance. It is only approximate, but if used judiciously it will be found correct. Of course, its use is restricted to pure night work, as I do not believe in the methods adopted by some photographers of giving a short daylight exposure first and then waiting until darkness has set in to complete it. Such methods are quite unnecessary, and only give flat results, not to mention the time wasted.

TABLE OF APPROXIMATE EXPOSURES FOR NIGHT WORK.

Subject.	Weather.	Month.	Time.	Stop.	Plate.	Exposure.†
Open street scenes, squares, panoramas, views, illuminations, extensive harbour scenes, etc., well lighted with either electric or incandescent gas.	Clear, cloudless, with or without frost, after a heavy fall of snow, with a full or half moon. After a shower of rain, with wet pavements, etc.*	From Sept. to Feb.†	8.30 p.m. to 3 a.m.‡	f/11.§	"Seed" Ilford	15 minutes.
					Monarch. Imperial Special Rapid.	20 "
Country scene with very little or no artificial lighting.	Only possible under above weather conditions.	Ditto.	"Seed."	30 "
					Ilford Monarch. Imperial Special Rapid.	40 "
Close views in small streets or at street corners, in dark squares not too well lighted, principal objects in foreground.	Ditto.*	Ditto.	"Seed."	20 "
					Ilford Monarch. Imperial Special Rapid.	30 "
					Imperial Special Rapid.	40 "

* Any other conditions than these, such as no moon, very dark and overcast, cloudy, no rain or wet reflections, no snow, add ten minutes.

† During summer months five minutes should be deducted when the sky is cloudless.

‡ During summer months 11 p.m. to 2 a.m.

§ Stop value the same as for daylight work.

¶ I have obtained a negative with an Ilford Monarch, Cooke lens f/6.5, and an exposure of fifteen seconds. The above exposures are very full, and it may be necessary sometimes to shorten them; but it is advisable not to do so if possible, unless working with a lens having a full aperture of 3.5 or 4.5, when the exposure may be reduced to a fraction of a second. The above table remains as it was first published by the writer, the aperture f/11 being adopted because this aperture is available for every photographer possessing a camera.

In the dark room commences the real work of night photography. In the first place, cleanliness has to be strictly observed—clean dishes, clean hands, clean solution free from sediment, and a perfectly safe light. Whatever developer we may use, it must be diluted down very considerably; quick developers such as paramidophenol, more so than slow ones such as pyro-soda, for our plate has to be coaxed up slowly, not driven or forced. As a rule a plate should not be developed in less than twenty minutes or over forty minutes; generally speaking, it may be finished in half an hour. The reason for failure by many who attempt night photography is that they treat the plate as they would a daylight exposure, and use a strong developer. As a consequence, up flash all the high-lights

black and dense, and the shadows—well, there is nothing else but shadows when the plate is fixed, with a lot of black circles indicative of light. Therefore, dinna forget to "drown the miller" and dilute well—it's no' a drink.

As to developers, there is nothing like pyro-soda, and I can hear every photographer echo these sentiments for his own favourite developer, whether it be pyro, hydroquinone, or any one of the many different preparations to be found on the market. We all swear by what we have got into the way of using, therefore I would advise no change for night work, but simply to dilute freely the developer we like best.

In using pyro-soda too much developer in a diluted state should not be made up at once, as in this condition it is rapidly oxidised and stains the negative. For this reason a plate should not be left longer than ten minutes without changing the solution.

Stain may be removed by an acid permanganate bath, but chemical fog should be absolutely avoided. A common source of chemical fog is brought about by the oxidation of sodium sulphite to sodium sulphate. In the cinematograph industry this is an everyday occurrence owing to the very large quantities of chemicals used at a time to make up the big developing baths, and, as a result, a very large percentage of the sulphite used is really sulphate, and I have seen cinematograph film chemically fogged in less than a minute upon immersion in such a bath. Oxidation of sodium sulphite takes place in the dry state, and it is essential that air-tight jars should be used for storage—in fact, all photographic chemicals should be kept in air-tight jars, with the exception of hypo.

The formula I use is the "Imperial Pyro-soda," made up as follows:

"IMPERIAL PYRO-SODA" DEVELOPER.

Stock Solution.		No. 1.
	Pyrogallie acid..... 1 ounce	Stock solution 3 ounces
	Potassium bromide 60 grains	Water (boiled), to 20 ounces
	Potassium metabisulphite .. 50 grains	No. 2.
	Distilled water, to 12 ounces	Soda sulphite 2 ounces
		Soda carbonate 2 ounces
		Water (boiled), to 20 ounces

For normal daylight exposures use equal quantities of No. 1 and No. 2.

For developing night exposures use four drachms of No. 1 to five drachms of No. 2 in about sixteen ounces of water. To finish off a plate rinse it in a little stronger solution—viz., one ounce of the normal developer (equal parts No. 1 and No. 2) in eight ounces of water. This must not be allowed to act on the plate longer than one minute; it is simply used to strengthen up the detail. Do not add bromide to the working developer unless with a camel-hair pencil to retard a too obtrusive high-light on the plate itself. If the plate is not rocked too much a certain amount of bromide is formed in the solution immediately over the high-lights, and helps very considerably to hold this back. One of the beauties of pyro is the amount of juggling that can be done with solutions No. 1 and No. 2; there are very few reducers to equal it in this direction.

The method adopted by Mr. Wild I would strongly recommend for the development of all night negatives taken at exposures less than three minutes, but certainly not when the exposures are longer than this. Very short exposures at night do not give sufficient time for extreme over-exposure of the high-lights and consequent halation. This method, too, is decidedly the best for the development of panchromatic or colour-sensitive plates that will not stand prolonged development. Mr. Wild used the Imperial Standard formula made up with one part No. 1 to two parts No. 2, and one part of hot water to bring the temperature up to 75°. To prevent frilling all dishes, rinsing water, and hypo should be brought to about the same temperature.

To develop the plate, the gelatine surface of which should not be fingered, it is placed in a perfectly clean white dish, film up, and flooded with the diluted developer; it is then covered up, and rocked well to free from air bubbles. After having been in the developer for a few moments the plate is removed, and either placed in a large dish with cold water, or put, film up, under a running tap, and held there whilst the backing is removed with a tuft of cotton-wool. The light should be turned down as much as possible without inconvenience, to prevent any chance of fog. Unequal development would take place due to draining off of the developer if we were to remove the backing without keeping the film flooded with water. Some photographers develop their backed plates without troubling to remove the backing until after development. This method is all right for quick, straightforward development, but I do not recommend it for night work, as it interferes with the judgment of density, and may be the means of introducing numerous pin-holes in the negative.

After the backing has been removed the plate and dish

should be well rinsed and then flooded with fresh developer sufficient to cover the plate about one inch deep. It is then covered up, and may be safely left *without continuous rocking for ten minutes*, a slight rock being given at odd intervals. *Never examine the plate by transmitted light; always look at it by reflected light as it lies in the dish* (see reproduction of a night negative in last week's BRITISH JOURNAL, p. 486), and before renewing the developer, which should be done every ten minutes, thoroughly rinse off the old stuff. To one not accustomed to the appearance of a night negative, it may be somewhat disconcerting to find next to nothing on the plate after twenty minutes' development; *but we must remember that our view is a night one, therefore the shadows will largely predominate and shadows in a negative are almost clear glass*. Do not examine the plate too much during development; I never look at mine until well over ten minutes. It is perfectly safe to leave it; the developer is weak, and cannot do any harm.

ROBERT DYKES, F.R.P.S.

(To be continued.)

MAPPING FROM AIR PHOTOGRAPHS.

[From the purely photographic standpoint the war-created art or craft of aerial photography can too easily be regarded as having been brought to a high pitch of perfection. It is quite true that by the combined efforts of opticians, camera constructors, and emulsion makers the obstacles which sheer height, the movement of the aeroplane or atmospheric conditions put in the way of obtaining well-defined negatives from the air have been almost completely overcome. Yet that, after all, is only half the battle. An aerial photograph is nothing except in so far as it fulfils a useful purpose. In the important work of map-making the following paper by Lieutenant-Colonel M. N. MacLeod before the Royal Geographical Society is a timely reminder, by an authority, of the distance the aero-photographic method has still to traverse before it can dispense with the surveyor to supplement or check its results. To anticipate Colonel MacLeod, a general conclusion to which he comes is that "for accurate work we cannot of course dispense with the surveyor altogether, and in hilly country, until we can devise some satisfactory form of stereo-plotter, the air photograph will not help us very much." Other geographers who discussed the paper shared this view, that aero-photo survey is a branch demanding further research, and that, more at the hands of surveyors and topographers than at those experienced in the purely photographic problems. Such an expression of opinion is not without its significance in reference to the ideas of photographic survey apparently held by the Royal Air Force, to which we devoted some attention last week, and which is further, though differently, emphasised by a letter in reply which appears on another page of this issue — EDS. "B.J."]

AMONGST the many innovations which the war has produced not the least interesting and important are the methods of survey and mapping which were introduced and developed in France to meet the needs of the fighting troops for accurate large-scale maps. These needs were consequent on the peculiar character of the fighting, and were not foreseen before the war. That they could be met at all was due to the aeroplane photograph, which was developed and exploited to such an extent that it is no exaggeration to say that the aeroplane camera became the strongest weapon of the "Intelligence" Staff and the topographer. Regarded thus, the aeroplane photograph can be considered in two aspects, one purely "Intelligence" and the other topographical. From the strictly intelligence point of view its primary function is to show what is on the ground at any moment, so that the intelligence officer, by studying successive photographs and thus watching the enemy's organisations, their nature, change, and development, is enabled to detect and forecast his military plan. Viewed from this standpoint, the "interpretation" of air photographs becomes of prime importance, and has become in itself a special study of great interest. From the topographical aspect, however, the function of the air photograph is not to show primarily *what* an object is, but to show *where* it is, and enable us to place it in its correct position on the map. It is with this latter aspect that I have been principally concerned and propose to speak; the two subjects, however, cannot be entirely separated, and the map-maker must, of course, always devote considerable attention, at any rate in war, to the correct interpretation of the photographs he uses. In point of actual fact, I think I am correct in saying that the interpretation of photographs as a special study followed some time after their application to mapping, and followed upon the elaborate organisation of "camouflage" by both sides. At first, that is in 1915 and 1916, little organised effort was devoted to concealment from

the air, the interpretation of photographs was comparatively simple, and their study was directed almost exclusively to correcting our maps and plotting thereon the enemy's and our own trenches and other defensive works.

As stated above, the need for large-scale maps had not been foreseen before the war, consequently the first aeroplane photographs, taken early in 1915, found us without any proper organisation for making use of them. Attempts were made by the Intelligence Branch of the General Staff to correct the then very imperfect maps from them; but without success, for the reason that, though the photographs showed all the principal topographical features in great detail, there was no means of determining their exact scale or the amount of distortion due to the camera not being truly vertical at the moment of exposure of the plate.

This difficulty can be overcome in two ways: one by the invention of mechanical devices for measuring the tilt of the camera and its height at the moment of exposure, and the other by determining on the ground the correct positions of a sufficient number of points which can be identified on the photographs and deducing the scale and distortion of each photograph by comparing the relative positions of such fixed points as appear on it with their true relative positions as fixed on the ground. In France we devoted little attention to the first, and all the methods of plotting we used postulated a sufficient number of fixed points, determined on the ground, or by some independent means, which formed the framework of the map. How this framework was provided has already been described to the Royal Geographical Society by Colonel Winterbotham, and I will not, therefore, say much about it. The enemy, however, I think, almost certainly employed some mechanical device for measuring the amount of tilt. They also, I think, mark on their photographs the focal length of the lens used and the height at which the photograph was taken. I do not, however, know anything about these devices, and must, therefore, confine

myself to describing the methods of plotting used by ourselves and the French, and such German methods as have come to our knowledge from captured documents.

On any air photograph of a country, like France or England the most conspicuous features are the roads, railways, and rivers; consequently, to plot a photograph by comparison with a framework, it is best that the framework should be formed of these features. In France this framework was provided either from the "Cadastre" or by a plane-table survey (when possible) of all the principal cross-roads, sometimes by a combination of the two. This framework was drawn out on a sheet of paper known as the "compilation diagram," and the first method of plotting used by us to fill in the detail depended on the fixation of a number of additional points by a system of prolongations and alignments depending on the principle of perspective that straight lines on the ground remain straight lines on the photograph, and on the use of proportional dividers for filling in the intervening detail. Corresponding points on the diagram and the photograph having been selected, the dividers were set by trial and error so that one end gave the distance between two points on the photograph, and the other end gave the distance between the same two on the diagram. The detail round them was then plotted point by point by measurement from these two fixed points, checked, if possible, from a third.

This method was naturally very laborious and slow, and was only accurate when the photograph was taken truly vertical, and the scale therefore uniform all over. This was rarely the case, and it was often necessary to plot as many points as possible from several photographs to find "mean" positions, and regard these as "ruling" points before proceeding with the plotting of the others. The results, when time permitted, were more satisfactory than one might have expected, but the process was slow, and it was not long before efforts were made to devise something better.

The next development was the use of the "camera lucida" to project the image of the photograph down on to an adjustable board carrying a tracing of the map framework, which could then be swung about until the "fixed" points on the photograph coincided with those on the map framework, when the draughtsman could draw in anything on the photograph by running over the lines with a pencil. This method was, and is still, I believe, largely used by the French, who used an apparatus known as the "chambre claire," consisting of a prism mounted over a board carried on a universal joint, the whole being carried on a horizontal slide at the other end of which is a vertical board to which the photograph is pinned. The photograph board can be moved backwards and forwards along the slide by a screw worked from the draughtsman's end.

This arrangement was tried by us, but was not found very satisfactory. The strain on the eye is very great, there is considerable parallax, and the adjustment is not very easy, particularly if the draftsman does not thoroughly understand the principles of focus and perspective on which the correct adjustment is based. The photographs, moreover, require treatment before they can be used, or the image on the paper is not sufficiently clear. The French commonly scraped out the roads on the photographs to make them appear bright white, and inked up the trenches in red and blue. I do not like the instrument, at any rate our instrument, for mapping work, as the strain on the eye is so great that the draftsman is often tempted to trace in only a few features and sketch in the rest by eye.

The next apparatus evolved was a cumbersome affair called a "projectograph," constructed by the British. In this the image of the photograph was projected by means of a lens and prism down on to a board similarly mounted horizontally on a universal joint, the arrangement being generally similar to the "chambre claire" of the French, except that the small prism of the "camera lucida" to which the eye is placed was replaced by a lens and a prism which could be focussed to give an image on the board. The apparatus was extraordinarily cumbersome, and suffered from the defect that the vertical photograph board could not be adjusted by the draftsman without moving away from the end where he could see the image. The whole also had to be enclosed in a black shroud to keep out the light. Each field survey battalion was supplied with one of these outfits. I eventually made good use of mine, but only after disintegrating it into its component parts.

In both this and the "chambre claire" I always found great

difficulty in adjusting the photograph and the "map" so that the image of the two coincided all over the photograph. The reason may have been that we had not a lens of the proper focal length, a point to which I will refer again later. In any case, it was this difficulty which was the deciding factor in leading us on to the apparatus we eventually constructed, which involved the use of an enlarging camera, and for which many parts of the dismembered "projectograph" came in very useful. Having first prepared the "compilation diagram," the photograph was compared with it and the points common to both, usually cross-roads, but sometimes churches or buildings, were marked on the photograph. The negative was then borrowed from the R.A.F., these points marked on the back of it, and joined up with fine black lines. From the compilation diagram a trace was made of the corresponding figure. The negative was then put into the camera, and the image thrown on to a copying board mounted vertically on a universal joint. By moving the board backwards and forwards and twisting it about, the image was adjusted to fit the diagram as closely as possible. Provided the photograph was somewhere near the vertical, as most of those which we used for mapping were, the adjustment was not very difficult. A piece of sensitised paper was then pinned on the board and a print taken. From this print the map detail was traced on to the fair drawing.

To adjust the image correctly, at least four fixed points are necessary on each photograph, and these should be of course in the same plane or as nearly so as possible. No adjustment in a camera will correct distortion due to difference of level on the earth's surface. No amount of juggling with the negative or the board, for example, will make a vertical wall, photographed from an angle and appearing as a narrow oblong on the negative, appear as a Euclidean line on the final print.

The adjustment of the image also depends on the focal length of the lens used in the enlarging lantern.

For correct adjustment the focal length (g) required is given by the equation

$$g = \frac{tf}{p+t} \text{ (assuming that the lens is correctly centred)}$$

where f = the focal length of the aeroplane camera,
 p is the scale of the negative,
 t is the scale of the map.

It will be seen that when p and t are equal, the focal length of the lens used in the enlarging lantern should be half that of the aeroplane camera lens.

In practice it is not possible to use a different lens for every variation of p and f , and it can be shown that correct adjustment can be obtained with a lens of any focal length by using a "rising front" in the enlarging lantern and displacing the lens a certain distance from the perpendicular to the centre of negative.¹

The proof of this is rather too long to give here, as are the calculations giving the amount of this displacement and the inclination which must be given to the copying board.

The latter is given by the equation

$$\sin \phi = \frac{g(p+t)}{ft} \sin \theta$$

where ϕ is the inclination of the copying board to the vertical, the projection of the horizontal line through the centre of the aeroplane photograph being taken as axis, and θ is the inclination of the negative to the horizontal (*i.e.*, the tilt).

The displacement, which must be in a direction at right angles to this same axis, is given by the equation

$$d = \left(g \frac{p+t}{t} - f \right) \tan \frac{\phi + \theta}{2}$$

When θ is small (less than 4°), and p and t are nearly equal, then, if we use in the enlarging lantern a lens of the same focal length as that of the aeroplane camera, we have

$$\phi = 2\theta \text{ and } d = f \tan \frac{3\theta}{2}$$

¹ Commandant Roussilhe, of the French Army, has constructed an enlarging camera which is said to give a correct projection and exact focus, but the preliminary calculations and adjustments are said to take four hours for each photograph. When adjusted, however, it can be used for photographs taken at any angle.

Or, to take a concrete example, if $\theta=4^\circ$

$$\phi = 8^\circ \text{ and } d = \frac{f}{10} \text{ nearly.}$$

The final print is rarely clear enough to trace directly on to the fair drawing, and it is generally necessary to ink up such features as have to appear on the map in vermilion, or other suitable colour. This, however, does not take long, and can be done by comparatively unskilled men.

This method proved far the quickest of any we used, and also the most accurate. It has the further very great advantage that every feature, however small, visible on the photograph can be drawn in without difficulty on the map correctly to scale in its correct position. It is, for example, perfectly easy to draw in every individual tree in an orchard or along a road exactly in its correct position. The print is also a permanent record which can be filed with the other mapping material for future reference, if required.

Used in this way the air photograph can hardly be improved on as a means of making large-scale maps. In 1918, after we got this apparatus into satisfactory working order, my Battalion mapped more than twenty 1/10,000 sheets, each 8,750 by 5,500 yards, in three months, employing about six topographers and twenty draftsmen on the work; or about five square miles per man per month. This included the plotting of the grid and trig. points, preparation of the compilation diagram, plotting of the photographs, and the fair drawing of detail, water, and contours on separate plates: the whole process of survey, except the triangulation, typing of names, and the reproduction.

This map was never systematically checked, but the tests applied to our maps in the field were pretty exacting, and no serious errors were detected. I am confident that in flat country, particularly in close, well-wooded country such as in the region round Hazebrouck to which the above figures refer, mapping from air photographs in this way is incomparably quicker and just as accurate as any other method of survey at present known to us.

M. N. MACLEOD, D.S.O., Lieut.-Col., R.E.

(To be continued.)

DEATH OF MR. HENRY A. STRONG.

THE death is announced of Mr. Henry A. Strong, vice president of the Eastman Kodak Company, on July 26 last, at the age of eighty-one.

Mr. Strong was the oldest business associate of Mr. George Eastman in the development of the enterprise which has grown to its present world-wide dimensions. In 1881 Mr. Eastman had newly left the service of the Rochester Savings Bank, and was beginning the manufacture of dry-plates in quite a small way. He needed more capital, which Mr. Strong, the senior member in a Rochester whip business of Strong and Hanbury, supplied on the terms of a half-share in the dry-plate business, which was organised as the Eastman Dry Plate Company, Strong and Eastman, proprietors. This early association has been maintained throughout the evolution of the Eastman undertakings, and at the time of his death Mr. Strong, so it is stated, was the second largest stockholder in the Eastman Kodak Company.

FORTHCOMING EXHIBITIONS.

September 13 to October 11. London Salon of Photography.

Entries close September 2. Hon. sec., 5a, Pall Mall East, London, W.C.1.

October 13 to November 29—Royal Photographic Society—

Entries close September 19 (carrier), September 20 (hand). Secretary, J. McIntosh, 35, Russell Square, W.C.1.

RAJO PAPER.—Messrs. Rajor, Ltd., intimate that they have made improvements in the emulsion of their "Rajo" developing whereby an increased latitude and lengthened scale of gradation enable them to dispense with the three grades, vigorous, soft, and normal, and to issue the paper in one grade only, suitable for all classes of negatives.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Fitting-up the Retouching Desk.

AUTUMN will soon be here, and when the clocks go back next month we shall realise it all at once, for it will be dark quite early, and retouchers will have to overhaul their arrangements for working by artificial light.

The makers of retouching desks seem to have paid little or no attention to this matter, with the result that retouchers themselves have to attend to it, as the desks are only arranged for daylight.

It is really an important matter, as it affects the eyesight of the retoucher considerably, a bad or badly arranged light soon compelling the use of glasses to ease the eyestrain, particularly where electric light is used.

A good oil lamp is usually considered the best artificial light to work by, but it is not always obtainable, and is also messy to clean and look after—both are items which waste the retoucher's valuable time. Moreover, retouchers usually seem to be expected to take the light provided and make the best of it, though this action on the part of the employer is not wise, for an arrangement quite comfortable for one retoucher is quite the reverse for another. For this reason I am going to suggest an arrangement which I myself use and find quite comfortable.

It is, of course, necessary to be as economical with light as possible even this winter, as we are still rationed, both for gas and electric light, and therefore where possible a lower powered bulb or mantle may be used nearer to the working aperture by the means I shall describe. This consists of three or four slots, with glasses, etc., running in them and working right on the desk itself.

The slots can be made from strips of three-ply wood, Academy board, or Winsor and Newton's Birchmore board. The strips are cut about two inches wide, and say nine inches long—depending, of course, on the size of the desk-opening. First a wide strip is fitted, then two narrower ones, half an inch above the edge of the wide one, then another wide strip, and then two more narrow ones.

All these strips are laid upon each other in a pile, till the required number of slots are formed for the glasses to run in. These are then carefully nailed all together, the nails being hammered over at the points so that the whole is held quite firmly together.

Next take first a piece of opal, half or whole plate size, according to the size of the opening in the desk—I have found half-plate to be quite large enough myself—next a piece of ground glass, or, failing it, a clean half plate glass matt varnished over and covered with a clean cover glass, "passe partouté" to it lantern slide fashion, to protect the varnished side.

Now fix and wash a couple of unexposed negatives of the required size, and before drying immerse for a minute or two in water coloured to a faint bluey-green with a few drops of the blue stain of the Vanguard Co. Very little colour is needed, but just make a pale glass, and then double the strength of the solution and make a more deeply stained one. These should then be dried, covered, and bound as was the matt-varnished glass.

The strips forming the slots should now be nailed or screwed on to the back of the retouching desk, at such a distance apart that the various glasses can be pushed easily to and fro with a touch of the finger or by the use of cords.

Where an electric bulb is used it can be hung on a flex, from a hook in the top back edge of the desk, a strip of wood with a V-shaped notch in the end screwed on the edge next the hook serving to hold the bulb out clear of the glasses, and yet near enough to save any waste of light. An inverted incandescent gas mantle can be used in the same way, but an upright one must be fixed to a stand or a high block of wood, to bring the light to the right height for comfort and convenience. For electric light I use the opal and one of the blue glasses together, the blue killing the yellowness of the light and making it approximately the same to work by as daylight—a soft, steady light. For incandescent gas I find the ground glass and pale blue glass will answer

well, being, of course, drawn over the opening in the desk against which the head to be retouched comes.

Even for daylight work I often find the ground glass a great convenience, where a very thin negative has to be retouched, making it easier to see the subtleties of half-tone and shadow, and all or any of the glasses can be instantly adjusted with one hand, without moving from one's seat and losing the focus of the eyes on the negative.

A little swing shelf, fastened to the side of the table and supported by a steel rod is also most useful to hold bottles, medium, etc., as it can easily be pushed out of the way, and the drawers fitted to most retouching desks are quite inadequate to hold bottles, and medium upset over the clothes has a tendency to ruin the clothes and cause much profanity. I also save the powdered lead from the retouching pencil, and find it makes an excellent stumping chalk, quite free from grit and of a good black.—G. E. H. G.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications for patents, August 11 to 16.

CAMERA ATTACHMENT.—No. 20,159. Camera attachment. M. W. Beyer.

PRINTING.—No. 20,071. Photographic printing apparatus. J. E. Bramwell.

FOCUSsing.—No. 19,847. Focussing devices for photographic cameras. W. Graham Brown.

CINEMATOGRAPHY.—No. 20,122. Cinematograph machines. A. La Rocca.

LANTERN-SLIDES.—No. 20,221. Photographic lantern-slides. W. J. Rider.

FILMS.—No. 20,084. Process for preparation of photographs or cinema films. G. Scelsi.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

AERIAL CAMERAS.—No. 128,609. (January 3, 1917.) A camera for taking a series of photographs from aircraft has an intermittently-operating motor for operating the film-feeding mechanism and the shutter, and timing-mechanism for starting the motor at regular intervals. The timing-mechanism is regulated by means operable from the pilot's seat. The motor for operating the film feed and shutters comprises four spring drums $J^1 \dots J^4$, fig. 6, the drum J^1 carrying a spur-wheel j^{14} for driving the film mechanism and a second spur-wheel j^{15} engaging the

Fig. 2.

spur-wheel j^1 , fig. 2, of the timing-mechanism, by which the tension of the spring j^{19} is maintained. The film-winding mechanism comprises spur-wheels M, F, fig. 5, which drive the winding-roll F through a friction clutch F^2, F^3 , fig. 6. Engaging with the pinion F^1 is a spur-wheel L^1 engaging gearing M^2, E^1 which drives a measuring drum E for measuring the required amount of film for each exposure, and also drives the roller blind mechanism. The spur-wheel L^1 carries on its axle ratchet-wheels L which are released in turn by pawls k^2 , the timing of which is controlled by the timing-gear. The timing-gear comprises a spring drum j^{19} wound by means of a handle j^{21} and driving an escapement-wheel j^8 engaged by an anchor escape-

ment j^9 attached to an adjustable pendulum j^{11}, j^{12} . The axle of the spring drum j^{19} carrier cams j^{20} which engage the levers K by which the pawls K^2 are moved. In the form shown in figs. 2 and 5, the adjustable pendulum comprises a lever j^{11}

Fig. 5.

carrying a pin j^{13} engaging a slot in the heavy disc j^{12} mounted on the pivoted arm j^{16} . The timing is regulated by altering the distance of the disc j^{12} from the lever j^{11} by means of a

Fig. 6.

cam j^{24} operated by a worm and worm-wheel. The worm may be rotated through a flexible shaft by means of a handle on the aeroplane. In the form shown in fig. 10, the adjustable pendulum comprises a lever j^{110} a slot in which engages a pin

carried by the lever j^{10} carrying weights j^{12} , the position of which is varied by means of a right and left handed screw j^{21} . The shutter arrangement comprises a roller-blind shutter G moving in the focal plane and a safety shutter R opened immediately before and closed immediately after an exposure is made. The roller-blind shutter is wound up by means of gearing $M^2, E^1, M^3 \dots M^4$ from the spur-wheel L , and is held against return by means of a ratchet-wheel and pawl I^1 . When sufficient film is wound and the shutter set, the cam j^{21} on the

Fig. 10.

timing-gear engages the lever N , which trips the pawl I^1 and releases the shutter. Immediately before the release of the shutter G , the safety shutter R is opened by means of a cam L^2 engaging a lever R bearing against the short lever R^1 . For use on aircraft, the apparatus is suspended in gimbals provided with dash-pots as described in Patent No. 128,593. In order to prevent the winding of the film from the supply to the take-up spool from disturbing the centre of gravity of the apparatus, the counterweight S^7 , fig. 9 (See Patent No. 128,593), is mounted on a lever S^5 connected through link-work to a roller S^2 kept in contact with the film on the roll C by a spring S^4 .—Arthur Brock, Junr., 131, South Fourth Street, Philadelphia, U.S.A.

AERIAL CAMERAS.—No. 128,593. (January 3, 1917). A camera for

Fig. 1.

Fig. 4.

Fig. 9.

taking a series of overlapping photographs from aircraft is suspended by yielding damping-means so that its axis is maintained

in the same direction in all positions of the aeroplane, and counterbalancing-means are provided to maintain the position of centre of gravity when the film is wound from one spool to the other. The camera A , fig. 1, is suspended by means of gimbals Y , dash-pots Z, Z^1 being provided between the camera and gimbal frame Y and between the gimbal frame Y and the framework X of the aeroplane respectively. The dash-pots comprise a cylinder Z , fig. 4, containing a piston Z^3 and provided with an adjustable by-pass Z^4 . The film is positioned and exposures made by means of a spring motor, and the timing determined by adjustable clock-work as described in Specification 128,609. To prevent the winding of the film from the supply roll C , fig. 9, to the roll F from disturbing the position of the centre of gravity of the apparatus, a counterweight S^7 is mounted on a lever S^5 connected through link-work to a roller S^2 kept in contact with the film on the roll C by means of a spring S^4 . The photographs obtained by this apparatus are utilised for plotting maps and determining the height and distances between different points, and also the height of the aircraft at which the photographs were taken.—Arthur Brock, Junr., 131, South Fourth Street, Philadelphia, U.S.A.

New Books.

HOME AND GARDEN PORTRAITURE.—The latest issue of the "Photo-Miniature" to reach our table has for its subject the making of at-home and garden portraits, and is illustrated by a number of examples of the fine work of Mr. Charles H. Davis in this field. Those who have read Mr. Davis's two articles in recent issues of the "British Journal" will be glad to avail themselves of this opportunity of comparing his practice with his precepts, and will, we are sure, think all the more of both. The text of the "Photo-Miniature" deals comprehensively with the practical work of portraiture in ordinary rooms and amid the other surroundings of a home, and is full of advice on the choice of the camera and lens and on the all-important matter of lighting. Our little contemporary is now obtainable again from Messrs. Houghtons, Ltd., 88-89, High Holborn, London, W.C.2, price 1s. 6d.; in America, from Messrs. Tennant and Ward, 103, Park Avenue, New York, price 35 cents.

THE ELEMENTS OF PHOTOGRAPHY.—Mr. Frank R. Fraprie, editor of "American Photography," may be congratulated on having made a really welcome and useful addition to the numerous elementary textbooks on photography. The little book, issued as "The Elements of Photography," is not an instruction manual of the ordinary kind, but a concise and rapid review, written in a way which the photographically inexperienced can understand, of the things which are current knowledge among photographers. It is a book which can be put into the hands of anyone anxious to take up photography and uncertain of the best way to go about it. Those who take it as their guide will have a very good general acquaintance with the processes which photographers use, and will save themselves from having to admit, after perhaps a year or two's experience, that they had never heard of such a process as factorial development or of the use of the rising front. Yet all of us who have had occasion to render assistance to the photographic tyro know that his extraordinarily small and promiscuous reading leaves him in ignorance of many of the things which he ought to know. "The Elements of Photography" provides as well as can be done a preliminary and sufficiently detailed presentation of photographic practice. It is issued from the office of "American Photography," 221, Columbus Avenue, Boston, U.S.A., price 35 cents in paper, 75 cents cloth bound.

BLACKPOOL BEACH PHOTOGRAPHY.—A raid upon photograph-sellers on Blackpool sands had a sequel at the police-court on August 22, when nine young men were fined for infringing the bye-laws by selling photographs within a forbidden distance of the Promenade. The acting chief constable said it was not fair such men should come into the town and do what they were doing in summer time. He asked for salutary penalties. Fines of 40s. each were imposed on Israil Kwasneck, A. Cohen, Leonard Smith, Alex. Farley, Arthur Attenbury, Robt. Dwyer, Dorothy Dwyer, and Harry Mackson. Cohen was fined 40s. in each of two cases. The magistrates also prohibit the taking of photographs on the sands or of bathing parties.

New Apparatus, &c.

The Ensign-Duplex Safelight Lamp. Sold by Houghton's, Ltd., 88-89, High Holborn, London, W.C. 1.

A VERY workmanlike lamp for the dark-room and one embodying a new feature of design has just been introduced by Messrs. Houghton, primarily for the use of professional photographers. Novelty and practical usefulness are qualities which do not always go hand in hand. We should be reluctant to accord praise to an article of use merely on the ground of some novel element of design, for we have seen too many examples, among photographic requisites, of the desire for "something new" leading unmistakably to the sacrifice of utility in practice. But in the "Ensign-Duplex" lamp the novel element is a distinctly useful feature which adds to the comfort and efficiency of the lamp in ordinary dark-room work. It consists in providing a safe light in the flat top of the lamp as well as in the sloping front. The illumination cast upwards from the top of the lamp thus renders visible the contents of shelves, against and below which a lamp stands as a rule, and thus rescues the bottles of stock solution, graduates, and the like from the

found gloom in which usually they are plunged. Moreover, by reflection of the light from the walls and ceiling, the dark-room obtains a low general illumination which, in the case of a small room, may extend to every corner, and in any case greatly contributes to comfort of working.

In addition to this feature special to it, the new lamp is of excellent design. It is of ample size, measuring inside about 10 x 10 x 12 ins., and the upper part of its sloping front accommodates the electric lamp in a position where no direct rays are emitted through the front or top safelight, but instead a very even flood of illumination by reflection from the matt white walls of the lamp. The safelights are transparent, as they quite well may be in so well a designed lamp. They are obtainable in five varieties: yellow, for gaslight papers; light and deep orange, for bromide papers and slow plates; red, for rapid plates; and green, for panchromatics. Two safelights are included with the lamp, at the price of £1 18s. 6d., together with 9 ft. of electric cable. Extra safelights are supplied at 5s. 6d. each.

A BOOT ACCESSORY.—Taking their cue, no doubt, from the nursery rhyme of the "Old Woman Who Lived in a Shoe," the Pyram Manufacturing Company, Dunbar Road, New Malden, Surrey, have introduced, as a studio accessory for photographers, a papier mâché boot of length about 32 ins., and thus big enough to allow of a fair-size child sitting in it. No doubt there are numbers of mothers whose artistic taste is such that they would be attracted by a portrait of a baby in these novel surroundings. We can well believe that it is so, for do we not remember a postcard, which had a large sale and led to litigation, in which a popular actress was shown emerging from an egg. The unusual will always secure popularity simply on the score of its novelty, and we can certainly say that the Pyram Company has imparted a high degree of realism to this boot accessory of theirs. It is an

old boot, with the uppers very much creased and the toe dented in, all of which heightens the effect when a pretty child of two or three years is seated in it to have his or her photograph taken. The accessory is supplied at the price of 30s.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

CROYDON CAMERA CLUB.

LAST week Mr. A. E. Isaac, an original member of the club, who never looks any older, gave a very practical evening on "Gas Fitting," one unsuited for detailed notice in the absence of diagrams. The majority will wisely leave this business to the accredited professional, as the laying and joining of iron gas-pipes calls for tools in these days costing much good money. On the other hand, compo' pipes are far easier to tackle, do not require expensive tools, and when hidden by plaster readily absorb any nails driven into the walls.

The catalogue sizes of gas pipes are rather astonishing to the uninitiated. To take one instance from many examples:—A "3/8-in." brass tube is equivalent to a "1/2-in." iron pipe, and both will screw into the same socket. Outside diameters in the one case, and inside in the other, explains this, but does not account for the fact that stated and actual sizes are often not in accordance.

Among other feats only possible to an expert, Mr. Isaac soldered two compo' pipes together in little less than no time. This led Mr. Harpur to try his hand, and for half-an-hour or so he wrestled with the problem, largely employing the blowpipe as a self-ejecting spittoon. Finally, an irregular mass of solder collected round the alleged join, upon which he triumphantly seized a piece of cotton-waste and dexterously wiped the pipes apart again. A most hearty vote of thanks was accorded to him and to the demonstrator.

The versatile nature of the informal session was again illustrated the previous week, when Mr. Sidney Tatchell, R.I.B.A., gave a highly interesting lecture on map-making, recalling infant days when the drawing of maps was welcomed as an escape from depressing instruction, particularly when the sporting element entered with configurations from memory. In point of originality these put to shame the finest ordnance productions.

From the lecturer's remarks it became apparent to all that not only is map-making a truly scientific pursuit, but accurate and rapid map reading is by no means so easy as some might suppose. To all intents and purposes it may be said that an expert ordnance map reader can clearly visualise the region the map represents, even to determining from any standpoint whether the visibility of distant hills is eclipsed by nearer elevations.

It is not possible to deal with the many useful points discussed, the most important tip, possibly, being that the letters "P. H." in ordnance maps indicate a source of great comfort to weary pilgrims, provided "P. H." is not closed, or run out of beer. Various maps from half an inch to 25 inches to the mile were shown, also a wonderful built-up model of a landscape; the full scale map which accompanied it showed clearly the principles involved in map making. The one inch to the mile ordnance maps, he said, will be found the most generally useful. It is to be noted that unless shown to the contrary all maps are drawn north and south, and in the smaller ones footpaths indicated are not necessarily rights of way.

In the discussion, Mr. Witterick first gave tongue, for in some

mysterious manner a map on the wall had been quietly but persistently insulting his intelligence, judging from his injured air and expostulations at the end of the lecture. Mr. Sellors had not quite grasped "contour lines," and asked many questions with apologies for his stupidity. "No apologies are necessary if one is born that way," politely remarked the "office boy," ever anxious to stand well with the powers that be. "Fancy a push-bike secretary not understanding contours!" supplemented Mr. Harper in pained astonishment. He then authoritatively learned, with no apparent satisfaction, that the graceful contours and majestic undulations abounding in his person could be expressed in map form, this information being elucidated by another question of the secretary. Mr. Clemes said that once in France, when steering by map and compass, owing to no allowance having been made for the difference between the magnetic and true north, a party, of which he was a member, missed the rendezvous by miles. The particular canteen aimed at was not mentioned. A most hearty vote of thanks was accorded to the lecturer for an evening of unusual interest.

Commercial & Legal Intelligence.

EASTMAN KODAK COMPANY.—The usual quarterly dividends of 1½ per cent. (being at the rate of 6 per cent. per annum) upon the outstanding preferred stock, and of 2½ per cent. (being at the rate of 10 per cent. per annum) upon the outstanding common stock, will be paid on October 1 to stockholders of record at the close of business on August 30.

LEGAL NOTICES.—A supplemental dividend of 6s. 8½d. in the £ has been declared in the bankrupt estate of Alfred Ernest Priest, photographer, 21a, Prince of Wales Road, Norwich, and residing at 51, Sprowston Road, Norwich. This dividend is obtainable at the Official Receiver's Office, 8, Upper King Street, Norwich.

NEW COMPANIES.

EGERTONS, LIMITED.—Registered on August 16, with a capital of £20,000 in £1 shares. Objects: To carry on the business of photographers, dealers in photographic and other films, photographic printers and publishers, dealers in cinematograph machines and films, etc. The subscribers (each with one share) are:—B. A. Gale, Glentwood, Hale, photographer, and A. D. Monlond, 93, Market Street, Manchester. B. A. Gale signs as "director and manager." Registered office:—45-49, Oxford Road, Manchester. Private company.

GUILD OF ILLUSTRATORS, LIMITED.—Registered on August 16 with a capital of £500 in £1 shares. Objects: To produce, reproduce, publish and deal in drawings, designs, prints, maps, photos, cinematograph films, lantern slides, microscopic sections, slides, and illustrations, to act as agents for artists and others, etc. The subscribers (each with one share) are:—P. J. Ashton, 157, King Henry's Road, Hampstead, N.W.; R. Durham, 61, The Avenue, West Ealing, W.13; J. O. Parker, 10, Blenheim Park Road, S. Croydon; H. H. Poole, 66, Burnley Road, N.W.10; W. Webb, The Hermitage, W.7. First directors to be appointed by the subscribers. Solicitor: P. J. Ashton, 83, Avenue Chambers, Vernon Place, London. Private company.

News and Notes.

THE LONDON SALON.—Intending exhibitors may be reminded that Tuesday next, September 2, is the last day for the receipt of entries for the forthcoming exhibition of the London Salon of Photography at 5a, Pall Mall East, London, S.W. Exhibits require to be delivered on this day by hand.

Mr. G. R. BALLANCE, famous for his landscape photographs of Switzerland and Italy, intimates that he is closing the business

which he has temporarily carried on at 34, Birchwood Avenue, Muswell Hill, London, N.10. A permanent studio and works will be opened early in October at Mentone, A.M., France.

THE SUNIC RECORD, Messrs. Watson's organ of X-ray techniques, publishes in its July issue some interesting notes on the industrial uses of X-rays, gleaned from the recent conference on the subject. It predicts a much wider scope for X-ray operators, particularly those of real photographic experience, by employment in this field. The "Sunic Record" may be obtained on application to Messrs. Watson and Sons (Electro-Medical), Limited, Sunic House, Parker Street, Kingsway, London, W.C.2.

RAPID HALF-TONE BLOCK-MAKING.—The "Times" reports that M. Georges Koister, the art editor of the Paris newspaper "Le Matin," who is on a visit to London, expressed a desire to know exactly how quickly the "Daily Mail" could take a photograph and make a block of it for reproduction. The length of time mentioned by the art editor seemed almost incredible to M. Koister, and there was a sporting interest in the performance which followed. M. Koister and a friend were photographed on the Embankment at 2.40 yesterday afternoon. At 2.54 a proof of the photograph was handed to them, and at 3.14 the block from which the newspaper reproductions are made was finished. The complete process thus took 34 minutes, and M. Koister described the performance as a record.

R.A.F. PHOTO SECTION.—In comment upon our notes of last week, the "Westminster Gazette" writes:—The BRITISH JOURNAL OF PHOTOGRAPHY makes a very proper protest against the suggestion that the photographic section of the Royal Air Force shall be retained in existence to carry out a photographic survey of these islands. What possible value can there be in such a survey of a country every landmark of which is carefully mapped? To suggest that such a survey might be useful in a war in which this country were invaded is silly. It would all have to be done again for war purposes, and done from day to day. Our contemporary puts the matter quite rightly when it says that all that the Air Force can require is a small staff of technical experts "to study the mechanical, optical, and photographic requirements of aerial photography for the naval and military services." That can be adequately done by a score of men, and the remainder of the photographic section ought to be promptly disbanded.

A PHOTOGRAPHERS' CLUB FOR LIVERPOOL.

To the Editors.

Gentlemen,—Judging by recent letters in your columns, there is some chance of the long-belated photographers' union becoming a reality.

Although I am not an assistant, and such a union would be of no benefit to me, I must say that the sooner it comes the better, and I sincerely hope that want of enthusiasm and energy on the workers' part will not spoil the efforts of those who are trying to get them out of the rut.

For the last six months I have been hoping to inaugurate a photographers' club for Liverpool, but have made no headway owing to the dearth of premises. There is still a possibility of bringing it into being for the winter. If any interested photographer cares to address a post card to me at Hall and Ashton's Office, Africa Chambers, Liverpool, I shall be pleased. Such a

club might provide ways and means for mutual assistance which would be of value to Liverpool workers.—Yours sincerely,

J. RONSON HALL.

PREVENTING DOUBLE EXPOSURES: PRESERVING OX-GALL: SOFT FOCUS LENSES: CHARGES FOR BACKING.

To the Editors.

Gentlemen,—I have recently tried the following method of preventing double exposures, which, though it may not be original, I do not remember to have seen described: Insert a small piece of tough paper between the screw head and the notch in the spring of dark-slide shutter. It will fall out on the shutter being drawn, thus automatically indicating that the plate has been exposed.

Last week a correspondent inquired how to keep ox-gall. Ascertain your butcher's killing day, get a fresh gall bladder, and add, say, $\frac{3}{4}$ oz. undiluted formaline to the contents (about a pint). The instructions for its use are most ably given in No. 3083 of the "B.J."

There have been some recent queries *re* soft-focus lenses. Users of the $f/6.5$ Cooke lenses will find that diffusion can be obtained by unscrewing the front glass a little. It may not be generally known that by taking out the back glass of this lens and unscrewing the front glass to the maximum extent a useful long-focus lens is obtained. It must be stopped down to secure definition.

A fortnight ago a correspondent complained of profiteering in packing boards. Nobody seems to draw attention to the exorbitant charges made for backing plates. When it is taken into account that plates (unbacked) are sold at a handsome profit, is it not preposterous that Is. 3d. should be charged for daubing less than a pennyworth of backing on a dozen half-plates?—Yours faithfully,

OLD HAND.

THE PHOTOGRAPHIC SECTION OF THE ROYAL AIR FORCE.

To the Editors.

Gentlemen,—On reading the article under the heading of "The Photographic Section of the Royal Air Force," in your issue of the 22nd inst., I must express a feeling of surprise, for I did not expect to find in your pages an article which is written in such a reactionary spirit and based upon an obvious ignorance of the present position of aerial photography. It is true that the "Times" report is perhaps slightly distorted owing to its brevity, but the ideas underlying your article are too fundamental to be based on a newspaper report. I should therefore like to deal with some of the points mentioned, and to endeavour to correct the impression which they undoubtedly convey.

It is stated at the outset that "it would appear that there is a desire on the part of those associated with the Photographic Section of the Royal Air Force to maintain that branch upon a considerable footing." This is, I know, not the case, and further, from an intimate knowledge of the officer who is now in charge of the aerial photography in the R.A.F., I feel that he is a man who has the courage to say when any movement is considered to be a waste on the part of a Government department. The statement that every town, river, etc., should be photographed was distinctly made as a suggestion for those ex-photographic officers who had the courage to embark upon this class of work as a commercial venture, and it was never suggested that the R.A.F. should undertake this work. To dwell upon this point, I would commend the writer to go to some popular seaside resort and to enquire if there is an inch of ground which has not been photographed from every angle and the results sold as picture postcards. To quote the remark of a publisher of such postcards from a place not 1,000 miles from Blackpool: "We have photographed the old place inside and out, and the only position now left is from an aeroplane." A project of this nature has recently been mentioned in the daily Press, and, as its promoter was present at the gathering of photographic officers, it is obvious that the speaker was trying to encourage similar undertakings, knowing that the men so employed would form an invaluable reserve should we again find ourselves at war.

At present the main object of the Photographic Section of the R.A.F. is undoubtedly the development of new methods and inventions and the maintenance of a nucleus around which an efficient force, similar to that recently demobilised, might be again built up if necessary. The present photographic staff of the R.A.F. undoubtedly know how this can be done, for they had a large share in building up the enormous establishment during the war which "accomplished a great work with triumphant success," not always owing to the organisation of the flying services, but often in spite of it. They are sufficiently conscious of the importance and possibilities of their work to resent being thought of merely as the producers of pretty pictures, applauded by the Press and the public, whose work is now finished and who may be appropriately frozen out in the restriction of expenditure. One of the greatest troubles during the war was that the work was done entirely on an emergency basis, and that emergencies foreseen by the photographic officers were unheeded by other branches of the staff till it was almost too late to act. The policy of wait-and-see advocated in your article of the 22nd is exactly what we had to fight against throughout, and which did so much to retard the progress of the work.

I can by no means agree with the statement that the function of the Photographic Section has been to state its problems and to leave their specific solution to manufacturers. Although I have no wish to slight their truly splendid efforts to maintain our supplies, yet I think that, were they consulted, they would agree that in a great many cases not only the problem, but valuable suggestions for its solution, came from the Air Force itself. It is certain that if this attitude had been adopted by the sections working in the East it would have resulted in disaster, for problems reported in the summer of 1917 had received little or no solution at home up to the time of the Armistice.

To turn now to that very popular but not unimportant subject, wasteful expenditure, I am sure that the tiny band of photographic officers now left in the R.A.F. would welcome a question in the House of Commons on the numbers of the personnel now employed compared with those at the date of the Armistice, on the present expenditure, and as to the views held by the Maps Department of the War Office and by official surveyors in India and the Near East on the utility of further aeroplane photography.

Everyone admits that an Air Force of a limited size has got to be maintained, and when aerial photographic survey is one of the few things of real and permanent value which can be undertaken by aeroplanes, a derogatory article purporting to have the authority of the *British Journal of Photography* is specially to be deplored. For, while the question of the proved applicability of aerial photography to the correction of maps is still under consideration in so far as it affects England, it has been abundantly demonstrated to be of the greatest value abroad. The photographic mapping of great Eastern cities like Baghdad, Lahore, and Peshawar has saved Government survey departments thousands of pounds and years of labour. The rapidity of work, the excellence of detail, and the degree of accuracy obtainable in the maps produced on scales of 1/40,000 and 1 in. to the mile, in Palestine and Mesopotamia, show beyond all question the value of employing all available aeroplanes in co-operation with ground surveyors. When one considers that Afghanistan and much of the Indian frontier remains to be mapped, and that frequent requests for photographic personnel are coming from those working in the East, it is scarcely correct to speak of the amount of photography still required in the field as insignificant.

The experimental stages in this work were passed through in 1917, since when several thousands of square miles of country have been photographically surveyed, and there is no need for any useless work to be carried out, if the lines already laid down are followed. At the same time, there is ample need for the improvement of both apparatus and methods, and for bringing aerial work into connection with the voluminous science of photogrammetry, about which so little is known in England. Little, if any, of this work in British possessions or spheres of influence can be or ought to be left to civilian firms, though I understand that a firm has been approached with a view to carrying out survey photography in China.

The American Government, with its characteristic aptitude for taking up valuable new discoveries, is, it is understood, inaugurating an Aeroplane Photographic Survey in conjunction with the U.S. Geological Survey, while Canadian Government surveyors, who have been using ground photography so successfully in the past, are anxious to see the utilisation of aerial photography in the Dominion. The photographic staff of the Air Force quite realises the possibilities and limitations of this branch of work, but should be encouraged rather than discouraged to make the best of it.

Finally, as the writer of your article was prompted to lay such emphasis on the point that no lists of surplus war material offered for sale by the Government include aerial photographic equipment. I attach a cutting from a recent issue of the "Times" which may be of interest. [See footnote.—Eds. "B.J."] I might further mention that one of two aerial photographic companies have been for some time using surplus stores supplied by the Disposal Board for aerial photography. If the writer is in need of aerial cameras, etc., he should write for the complete list from "The Surplus Government Property Disposals Board, Caxton House," Tothill Street, Westminster, S.W.

As one of the demobilised officers who listened to the speech which has given rise to these articles, I believe that I shall have the entire support of many of my friends, both among those remaining in the Force and from the majority, who have returned to civilian employment, in the above remarks. We should welcome any question in the House of Commons with regard to our occupation during the war, or as to the work which we commenced. Should there be among your readers anyone who shares my beliefs in the great future of this work, I hear that the Air Force is still anxious to obtain a few more recruits for its Photographic Section.

H. HAMSHAW THOMAS.

Downing College, Cambridge.

[We are exceedingly glad to have the assurance of Mr. Hamshaw Thomas that the programme of an aerial survey of this country is not contemplated by the Photographic Section of the R.A.F., but was a suggestion to civilian photographic bodies. The question of the advisability of such a programme can very well be left to these latter. We are in agreement also with what seems to be the view of Mr. Hamshaw Thomas, namely, that the work of the Photographic Section in the immediate future lies in the sphere of the survey of territory, although we cannot agree with him that the methods and principles of aerial photographic survey have been so completely worked out that there is not the opportunity for any useless work to be done along the lines so far developed. As recent discussion among ordnance surveyors has shown, there is still by no means approximately complete agreement as to the economic efficiency of the aero-photographic method, nor as to the extent to which it can usefully replace or supplement the existing methods of the surveyor. On this account it requires to be admitted that the decision as to the employment of aero-photographic methods should be left very largely with the branches of the Service entrusted with surveying work. We gather, from what Mr. Hamshaw Thomas tells us of the steps which are being taken by the Government authorities in the United States and in Canada, that it is intended to have such aero-photography carried out under the supervision of surveying departments—plainly, the desirable course. The paragraph from the "Times" which is referred to by our correspondent reached us just after our issue of the 22nd had gone to press. It appears below.—Eds. "B.J."]

GOVERNMENT CAMERAS FOR SALE.—Photographs taken by airmen played an important part in military operations. The Disposal Board of the Ministry of Munitions now announces that, from time to time, apparatus suitable for aerial photography will be available for sale. Attention is also drawn to a quantity of cameras, plates, tripods, and other accessories suitable for ground work, and cinema cameras, together with a small quantity of films. The stock is in London, and information can be obtained at Caxton House, Westminster.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed (or reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

- B. G.—Formula for ordinary film cement consists of acetone and amyl acetate mixed in equal parts, and then as much clean celluloid chips or shavings dissolved in it to make it sufficiently thick for convenience in use.
- D. E. N.—In some cases the police authorities require a photographer canvassing for photographs to be taken to have a hawkers licence. You should apply for information at the nearest police office in the district where you propose to work.
- R. L.—There is no book on the mechanism of focal-plane shutters; in fact, no literature on the subject apart from the papers on the theory of the shutter and the patent specifications of particular types of shutter. We imagine that the latter may be of some slight use to you.
- C. E.—The business of outdoor photography and commercial photography now comes within the Retail Businesses Licensing Order, and you require to obtain a licence if you are newly starting such business. You should apply for the necessary form to the Secretary (New Business Licences), Iddesleigh Mansions, Westminster, London, S.W.1.
- C. P.—For photographic reproductions of works of art apply to the Autotype Fine Art Company, 74, New Oxford Street, London, W.1, or to Messrs. W. A. Mansell and Co., 405, Oxford Street, London, W. We do not quite know what you mean by Continental studies, but you might try the International Art Company, Florence House, Nassau Road, Barnes.
- C. L.—There is no method of retouching ferrotype for copying. The best thing you can do is to copy-enlarge upon a decent scale and then work up either the enlarged copy negative or a print from it, afterwards making a fresh negative from one or other of these. This is the method commonly adopted in working from these defective originals, and a very great deal can be done either at the negative or positive stage.
- W. P.—1. Six lamps, each of 1,000 c.p., should be ample. 2. Ten feet from the floor is as high as you need have the lamps; eight feet would do at a pinch. 3. Certainly, a great advantage to be able to bring the lamps lower for seated figures, and particularly for children. 4. Yes, each should be on a separate switch for economy of current, and for better control of the light. We can usefully refer to the "B.J." of October 26, 1917, containing a "Practical" article on fitting half-watt lamps. Our publishers can still supply at 4½d., post free.
- N. E.—The "Osram" half-watts are the original lamps of this type, and possibly are the best, though we doubt if there is any ascertainable difference in quality between them and the "Mazda," made by the Thomson-Houston Company. We believe there are other makes of half-watt than the above; in fact, we bought two only a day or two ago for home use, and they seem all right, but it is impossible to say whether they are better or worse as regards actinic value. For your studio we think four or six 500-watt lamps would be ample.

- M. N.—If the yellow stain is not very severe, you can probably easily remove it by making up a solution of bleaching powder mixed with about an equal weight of carbonate of soda (washing soda), say, 1 oz. of each in half a pint of water. Shake up this mixture and let the deposit settle, and use the clear or semi-clear liquid. If the stain is really heavy it will probably not yield to this method, in which case a very satisfactory process is that worked out a year or two ago by the Ilford Company, working instructions in which you will find in the 1917 Almanac, p. 353.
- K. L.—1. The best way for anyone not versed in the reclaiming of silver from emulsions is to dissolve the emulsion in hypo and throw down the silver with liver of sulphur. Certainly, there is a great deal more silver in unused plates than in negatives. Comparatively little of the silver in a plate is retained in the developed negative. 2. The bluish stain is probably the kind of bloom which forms with age, due to gas and other atmospheric fumes. Depending on its age, it can sometimes be removed by rubbing with hard rubber, or by slight treatment with an abrasive preparation such as "Fricol," of the Vanguard Manufacturing Co., Maidenhead.
- W. T.—Exposures are always pretty long with a gas lamp installation, averaging from 5 to 8 seconds with an $f/4$ lens and an ultra-rapid plate. Possibly your lens and plate are both slower, which may account for the longer exposures. The harsh lighting suggests that you have got the sitter too near to the light. If you treat the area of the illuminant as a window admitting daylight you get a fairly good guide as to how you are to place the sitter. The alternative, and more actinic light, is obtainable by magnesium flash. A very good model of lamp is sold by the Tress Company, 4, Rathbone Place, Oxford Street, London, W.1. The cost is, or was, about three or four pounds.
- R. K. K.—If the subject is large in the 5 x 4 print, the latter is quite big enough for sending to the Press, but if a figure is only small on the 5 x 4 negative, it is well to enlarge part of the negative to 5 x 4 or to half-plate. Except for subjects which it is thought a journal may devote a very large space to, there is no objection in making larger prints than half-plate. There is no objection to sending the same photographs to different papers; it is the usual custom to do so, or you could very likely make good use of a Press agency, which would show your work to all the London papers. Two such firms are Barrett's Photo Press Agency, 89, Fleet Street, London, E.C.4, and the Press Photographic Agency, 170, Fleet Street, London, E.C.4.
- II. P.—You do not tell us the diameter of the condenser, which latter affects the question. But if your condenser, as we imagine, is about four inches diameter, then you ought to have no difficulty in getting a clear, shadowless illumination with an $f/6$ lens of $5\frac{1}{2}$ focus. The best place for a diffusing screen is as near to the light-source as you can put it, but usually it answers every purpose to put it on the side of the condenser nearest the light. We should imagine that your trouble comes from the extended area and particular form of the filament lamp. A better light-source would be a filament of the focus type, although it is not very suitable for the vertical type of enlarger. If we were you, we should use a gas illuminant in the shape of the "Howellite" inverted incandescent burner, supplied by Griffins', which is a first-rate light for enlarging, and particularly suitable for a vertical enlarger.
- E. N. D.—Why not try the Vandyke method to obtain the ink line on glass, using the original sketch as a positive? Thoroughly clean the glass and then soak in a 10 per cent. solution of ammonia for two or three minutes, again rinse, and coat with the following solution:—
- | | |
|--|---------------------|
| Water | 10 ozs. |
| Process g'ne | $1\frac{1}{4}$ ozs. |
| 10 per cent. ammonium bichromate sol. | $1\frac{1}{2}$ ozs. |
| Ammonia (.830) | 3 drops. |
- Whirl dry. Use the original sketch to print through on to the sensitised glass. After exposure develop in water and then dye up, dry film, and roll up with a good black ink, and lay aside for two to three hours. Place in a 5 per cent. solution of hydrochloric acid to remove resist. You will experience a difficulty in obtaining a dense black image unless the glass is first coated with rubber or celluloid varnish.
- J. T. B.—1. Yellowness of pyro-developed negatives developed in a tank can generally be overcome by adding additional quantity of sulphite to the working developer. There is no need for you to alter your formula for the stock solutions, which is a fairly good one, although we do not agree with the practice of putting the carbonate and sulphite in the same solution. We would sooner have the 8 ozs. of sulphite along with the pyro. However, apart from that, if you dilute the developer with 10 per cent. of sulphite solution in part substitution of the water, you should avoid yellowness in the negatives. 2. Negatives on isochromatic plates should have all the qualities of those on ordinary. If you send us a negative or two we could advise you better, but, generally speaking, if you use the makers' formulae for the developer, you ought not to have the fog and appearance of over-exposure of which you complain. As a rule, an iso plate develops best with a rather weaker developer (more water) than one of the ordinary kind.
- J. H.—1. The Mackenzie-Wishart slide consists of an envelope within another, the pair holding one plate. These envelopes require to be used with what is called an adapter, which is a shallow box with a hinged back and draw-out shutter, which takes the place of the dark-slide in the camera, and is used for manipulating the two halves of the plate envelope. 2. Absolutely nothing better than a big changing bag with a couple of sleeves. We have used other contrivances in the shape of boxes and bags with windows, but our experience is that the ordinary bag is the best, and it is very easy to change plates by touch. 3. The most convenient pattern of trimmer is the trimming desk of the Merrett pattern, sold by the Adhesive Dry Mounting Company. The print is laid in position on a hinged desk underneath a guide, and the protecting portion trimmed by pressing down the desk. For very accurate trimming you cannot do better than supplement the use of such a desk by an ordinary draughtsman's drawing-board, T-square and set-square, using these to mark the print with pencil lines which can then be most accurately cut through in the trimming desk.

Line Advertisements.

Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.
(No reduction for a series.)	

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.
Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.
Displayed Adv'ts should reach the Publishers on Monday morning.
The insertion of an Advertisement in any definite issue cannot be guaranteed.

MAPPING FROM AIR PHOTOGRAPHS. By M. N. MacLeod, D.S.O., Lieut.-Col., R.E.	518	The Photographic Section of the R.A.F.	524
		ANALECTA	524
		ANSWERS TO CORRESPONDENTS	524

SUMMARY.

In searching for the cause of defects, such as fog in negatives, examination of the working conditions is as necessary as scrutiny of the negative. The former is much more likely to locate the cause than is the latter. (P. 514.)

In his article this week "Practicus" deals with the leakage of water through the studio roof. He describes methods of glazing which should prevent the nuisance, and has something to say on remedies which can be applied in emergencies. (P. 515.)

In the further portion of his article on night photography Mr. Robert Dykes, F.R.P.S., deals chiefly with the after-treatment of negatives of night subjects and with the making of prints and lantern-slides. (P. 516.)

The recent paper of Lieut.-Colonel M. N. MacLeod before the Royal Geographical Society on mapping from air photographs continues the description of methods used by the French and the British and by the Germans. It concludes with a brief summary of the further progress which requires to be made. (P. 522.)

Particulars of surplus aerial photographic supplies which are being offered by the Disposals Board appear on page 523. The photographic goods at present listed include many aerial cameras, lenses of focal lengths from 5 to 30 ins., and a great variety of printing papers. (P. 523.)

In the making of white-margin prints an immense amount of time may be saved by having ready to hand an outfit of card negative carriers, the aperture in the card forming a mask of given size and shape. (P. 513.)

The system of displaying a reduced price and of making good by extra charges is one which in the end probably does not pay a photographer. (P. 513.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

In a review of colour photography, Lieut. H. E. Rendall states his opinions, largely from practical experience, of the various processes, more or less in use immediately before the war, for the making of three-colour prints. In conclusion he outlines a suggested process of two-colour printing. (P. 33.)

The Colour Laboratory of the Bureau of Chemistry attached to the United States Board of Agriculture has published working details for the laboratory preparation of the colour-sensitising dyes known as pinaverdol and pinacyanol which are designated at Pv. I. and Pv. IX. (P. 34.)

Mr. S. G. Yerbury writes putting in a plea for further investigation of methods of direct photography as likely to be more fruitful than the three-colour processes currently in use. (P. 36.)

EX CATHEDRA.

Extra Charges. Some photographers make a practice of quoting an apparently low price for their work, and then endeavour to make it remunerative by making a considerable extra charge for modifications which the customer did not expect to pay for when entering the premises. For example, we find a man filling a window with postcards, say, at 3s. 6d. per dozen, and charging another eightpence for sepia toning, while an additional charge is made for a second figure or a slightly larger head. This is objectionable both from the point of view of the sitter and the photographer, and in the end does not tend to improve business. If different classes of work are done, it is much better to show plainly priced specimens of each, so that sitters can choose at the outset and not have a feeling that they have been rushed. Even better-class studios are not above this sort of thing, quite a disproportionate increase being made upon prices shown in the window for any modification in style. We have it upon the authority of one who has tried both ways that the abolition of extras, as extras, has resulted in a marked improvement in his takings. If the photographer looks at his own practices as he looks at those of the bootmaker who charges him sixpence extra for a pair of laces for boots already twice pre-war price, he will realise the feelings of his sitters.

White Margins.

It is often necessary to produce prints having a white margin which may be as narrow as one-eighth of an inch or several inches in width as the class of work may demand. Unless there is some system of preparation a good deal of time is lost in improvising and fixing masks, and unless these are properly secured there is always a risk of spoiling good paper. A plan which we have found to work well is to keep a special printing frame for the purpose with a good sheet of clear glass in it. This frame must, of course, be as large as the largest paper to be used; if the subject is not well centred upon the plate it must be larger. The next step is to provide several cards not thicker than the negative-glass, and to cut out openings into which the plate will exactly fit. Round the margins of these openings are fastened strips of passe-partout binding overlapping the edges so as to give the desired width of margin. All that has now to be done is to drop the negative into the frame, and when the print is not larger than the plate to lay the paper so as to correspond with the edges of the plate. For larger sizes register marks made of the same binding strips should be stuck on the card, so that the margins may all be uniform in width and square with the subject. If the subject has to be in an oval or circle, this must be cut out of black or red paper and pasted in the card frame instead of the strips. If a dozen or so of

these frames are made for each sized negative with different openings any negative may be fitted in a few moments.

* * *

Cap Caps. Nowadays, exposures made with the lens cap are by no means as common as they were years ago, and frequently we find expensive lenses devoid of these fittings. But, quite apart from their use as a means of exposing plates, a well-made cap should be regarded as inseparable from a good lens when the instrument is not in use, even if attached to the camera; while if it is usually taken off and stored separately, a cap should be fitted over each end as a protective measure. In this respect the modern shallow hood of the anastigmat lens seems to demand the protection afforded by the cap far more than did its predecessors of thirty years ago, when the hood of the instrument allowed the glasses to be set far back. Speaking of lens caps reminds us that many of the present-day photographers cannot make an exposure with the cap without running a serious risk of blurring the negative through shaking the camera. Some time ago we saw a photographer, whose roller-blind shutter had failed him, take off his lens cap to make an exposure with a sudden wrenching motion. The correct way is to remove the cap with a gentle circular screwing-off action, lifting it in an upward direction, and thus to some extent equalising the exposure of sky and foreground if the subject is a landscape.

TRACING DEFECTS IN NEGATIVES.

The perfect result in photography is dependent so essentially on the absence of the many conditions which can introduce defects that it is difficult for anyone but the individual worker to say with any certainty what is the cause of spots or fog or any of the miscellaneous ills which beset gelatine negatives. Yet, despite this fact, it is part of our daily work to do what we can to locate the cause of one defect or another in negatives which are sent to us by our readers. Without wishing to discourage any of these latter from their habit of seeking such help as we can give them, it must be admitted that in many cases all that we can do is to make a guess at the cause and to leave the correctness of our guess to the further judgment of the inquirer. In some instances, perhaps, our suggestion may indicate a cause which had not been thought of; in others, no doubt, such cause had been definitely eliminated by the inquirer's knowledge of his working conditions. At any rate, it seems useful to offer a few notes on the general plan which may be followed in endeavouring to come to a decision as to the cause which makes a negative defective in one way or another.

Probably the defect which is most frequently brought to our notice is a general fog or veil over the negative. In this connection it seems not to be realised by many querists that very different causes may lead to an almost identical effect, and that the solution of the problem lies more in an examination of the working conditions than of the negative. From the latter it is impossible to say whether the fog is light fog or chemical fog, that is to say, if it is produced by extraneous action of light in conjunction with a properly compounded developing bath or has its origin in the faulty development of a plate which has been exposed only to light reaching it in the correct manner through the lens. Certainly the negative does give some slight guide in these circumstances—namely, by the appearance of the narrow margin of the plate which usually is shielded from light during exposure in the camera by the rebate of the dark-slide. If this narrow edge is reasonably clear and free from fog in the negative,

it follows that the cause of the fog must lie in the kind of image which is formed on the plate, and cannot very well be the result of a faulty developer or an unsafe dark-room light, either of which would affect the plate up to its extreme edges. Thus the condition of these rebate edges in the negative is a first hint of the direction in which to look further for the cause of the defect. If the edges are clear, the fogging of the plate is most probably due to a dirty condition of the lens or to the illumination of the inside of the camera to an extent which can cause a general veiling of the plate during the period of exposure. The two things often go hand in hand, but even when the lens is free from a coating of dust which causes it to distribute light on to the plate somewhat like a window of frosted glass, the conditions may be such that the fog comes from light reflected from the interior of the camera on to the plate. The wide-angle over which the modern anastigmat covers is responsible for fog from this cause: the interior folds of the bellows come within the cone of illumination from the lens and cause veil by reflection on to the plate. It is here that a lens-hood or a diaphragm placed within the camera proves to be of decided benefit. The reputation of the older types of R.R. and single lenses for bright images probably arises as much from their deficiency in angle of illumination as from their optical qualities *per se*. Moreover, the use of the wider angle anastigmat has extended along with a reduction in the dimensions of cameras and with the growth in popularity of the taper bellows, which explains why a given lens will yield brilliant negatives free from any suspicion of veil on an old-fashioned camera of the square-bellows type, whilst an exactly similar lens in a taper bellows camera will give trouble from veil.

When we come to the causes of general fog over the whole area of the negative one of the things which will, of course, occur at once is want of safety in the dark-room illumination. This may arise either from leakage of white light into the dark-room or from passage of actinic rays through the safelight of the dark-room lamp. A little hint as regards the former is worth mentioning, since we know that it has proved the means of tracing leakage of light which remained undetected until it was used. It is simply to lay a piece of mirror in the empty developing dish, and with all lights extinguished to examine the mirror for any reflection of light. It may happen from the special way in which a dark-room has been fitted up, often by partitioning off part of a larger room, that outside light finds its way to the developing dish from a source which cannot be seen unless one can take a look round exactly from the position which the plate occupies. The mirror enables one to do this. As regards the dark-room light itself, the production of fog from this source is readily detected by the usual plan of laying a plate in the developing dish in total darkness, at the same time laying one or two coins on it. If then the dark-room light be turned on and the developer applied for, say, ten minutes, the presence of any insecurity from this cause should be revealed by the production of the outlines of the coins on the plate. In making such a test as this it is too often forgotten that the safety of a dark-room light increases considerably with the distance from it; it will not do to make the test with the developing dish 3 ft. away and then expect an equal safety of illumination if plates are handled or developed close to the lamp.

If tests for the unsafeness of the dark-room light yield only negative results, the trail for fog must be followed in the composition of the developer or in its contamination during use. We have known of cases where fog which for a time baffled detection was traced in the end to using the anhydrous instead of the crystallised form of sodium carbonate. By practically doubling the proportion of car-

bonate in the developer it is obvious that, with many formulæ, fog is bound to be produced. But perhaps the most common cause is contamination of the developer with hypo, brought about very often through belief that the dark-room towel, which is regularly in use for wiping fingers which have dabbled in the fixing-bath, actually

cleans them thoroughly from hypo solution. As we emphasised in a note not long ago the dark-room towel too often serves as a distributor of hypo, and a rule should be made of keeping it to its proper purpose, which is for drying the hands after they have been rinsed from any chemicals under the tap.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).
The Postcard Studio (March 14).
The Printing-Room (March 21).
About the Reception Room (March 28).
Home Portraiture (April 4).
Portable Studios (April 11).
Copying (April 18).
Handling the Studio Camera (April 25).
More About Lenses (May 2).

Enlargements (May 9).
Advertising the Studio (May 16).
Mounts and Mounting (May 23).
Business Methods (May 30).
Photographing Children (June 6).
Portraits of Elderly People (June 13).
Something about Lenses (June 20).
Hand Cameras for Professionals (June 27).
The Dark-Room and Its Fittings (July 4).
Plates and Their Work (July 11).
Apparatus Repairs and Renovations (July 18).
Posing the Head (July 25).
Intensifying Portrait Negatives (Aug. 1).
Workshop Jobs (August 8).
The Personal Factor (Aug. 15).
The Keeping of Negatives (Aug. 22).
Reduction of Negatives and Prints (Aug. 29).

LEAKY ROOFS.

THERE are few who have worked in the ordinary type of studio who have not, at one time or another, experienced the misery of working under a roof which was not water-tight. I have known well-built places, where no expense was spared in erection, which possessed roofs which it seemed impossible to keep sound by any ordinary methods. Time after time the glaziers were called in, but their labour only resulted in a temporary alleviation of the trouble, a few months, or even weeks, producing another crop of leaks.

There are two principal causes of the trouble in question, one being the failure of the putty, or other fixing material, and the other siphoning of water between the overlapping edges of the glass. The former is the most usual and the most troublesome, as the latter may be entirely avoided by having a narrow overlap, only, say, a quarter of an inch. This also avoids the disfiguring bands of dirt which collect between overlaps of half an inch or more. Moreover, the margins of the glass should not be in actual contact. The former is due to the putty having lost its tenacity and allowing water to penetrate between the sash bars and the edge of the glass. To avoid this, it is a good plan to dispense with putty altogether when building a new studio, or entirely replacing the roof, as there are several good systems of what are called "metallic" glazing which I shall refer to later. When designing a studio it should be borne in mind that the steeper the pitch of the roof the less is the likelihood of leaking; so that we can secure entire immunity by adopting Robinson's suggestion of a high side light only, as then there is no roof to leak. Next to this comes the single slant with its angle of 62 degrees. With this slant the water drains away so quickly that little, if any, will pass through even if the glazing be faulty.

The great majority of studio roofs have wooden sash-bars, and these seem to be more affected by climatic changes than iron ones. One would naturally suppose that iron would expand and contract to a greater extent with given change of temperature than wood, and possibly it does, but iron is waterproof

and does not absorb water, so that this may account for the apparent anomaly, for we have all noticed that it is after a long spell of dry, rather than hot, weather that the leaks put in an appearance. A roof with metal sashbars, and what is called lead glazing, is more costly than a wooden one in the first instance, but in the long run will be found cheaper, as, except in case of breakage, no labour will have to be expended upon it, and all damage to blinds, furniture, and apparatus will be avoided. There are various systems of which particulars may be found in the building trade papers, but in principle they are the same: a metal bar, somewhat similar to the wooden ones, but with a small channel down each side, coming under the edges of the glass. When the glass has been placed in position a broad strip of soft lead is screwed on to the middle rib and pressed down so as to cover the edges of the glass to about the same extent as the putty usually does. This construction has the additional advantage of permitting a broken pane to be quickly replaced, no matter what the state of the weather may be.

With wooden bars the trouble is caused by the putty perishing and coming away from the wood, so that water can penetrate between the edge of the glass and that of the wood, and the problem is how to prevent this when building the studio and how to cure it if it happens. When sashes are made in the ordinary way they receive before glazing a coat of paint, usually pink in colour, which is called "priming." This paint is usually very poor stuff, some of it being innocent of white lead. For our purpose, before glazing, the rebates which are to hold the putty should be carefully coated with the best quality of paint—i.e., pure white lead, linseed oil, and turpentine. These materials are unfortunately very expensive just now, and there are many substitutes in use, so that care should be taken to get the real thing. When this coat of paint is dry, but not hard, the glass should be bedded into a thin layer of putty, then a thin coat of paint run along the edge where the putty will come, and finally the putty put on and smoothed in the usual way. No more putty than is needed should be used, as a thick fill-

of putty is more likely to shrink away from the glass than a thin one.

Now, a word as to putty. This should be made of whiting and pure linseed oil, and there should be plenty of oil. Some of the war-time putty is very poor stuff, so that it is better to pay a little more to have it right. As a matter of fact, it is easy to make one's own putty and to work into it any remnants of paint which by virtue of the white lead will add to its durability. As it has been shown that the weakness of putty lies in its liability to harden and crack away from its surroundings, it is to be presumed that a putty which would never become really hard would be a desideratum. Mr. F. A. Bridge claimed that a mixture of two parts of putty and one part of Stockholm tar possessed such a quality, and that he had prevented leaks in his studio for many years by its use. I have never used this mixture myself, but I knew Mr. Bridge's studio well, and it always appeared watertight. A very durable glazing may be made by omitting the top fillet of putty and putting instead upon the painted margins of the glass and wood a strip of strong tape soaked in paint, working this into contact with the surfaces by means of a medium-sized sash tool. When this is dry it should receive another coat of paint, which can be renewed from time to time as it becomes affected by the weather.

When leaks occur in an old roof it is next to useless to try to cure them by filling in the gaps left by the old putty. This may act as a temporary stop, but as soon as there is a spell of fine weather the entire row of glass should be removed and replaced according to one of the methods just described. I may just hint that it is advisable to keep two or three sheets of glass of suitable size in stock so that no time need be lost in the case of a smash occurring in wet weather. If a pane happens to get cracked so badly as to allow water to enter it may be temporarily repaired by painting a band over the crack and applying a strip of tape or calico, as recommended for glazing. This is rather unsightly, but is efficacious.

There is a way of dealing with a leaky roof which has the advantage that it can be done from within, and that no skilled labour is required. It consists in the application of a light zinc channel underneath the sash-bar, so that any water which finds its way through is caught and led away to where it can be conveniently collected. For each sash-bar to be treated we shall need a strip of zinc the length of the bar and about an inch wider than the inside surface of the wood. This is turned up on both edges so as to make a channel about a quarter of an inch wide and the same depth, being attached to the centre of the wood by screws about a foot apart. If possible this should be carried out into the open air, but if this is not possible a dish or jar must be placed to receive the drainings. This is perhaps rather a clumsy device, but has proved useful in many cases, especially in bad weather when nothing else can be done. It is, at all events, better than having to stand dishes about the studio, where they may be much in the way when working. Sash-bars with such side grooves are an article of commerce both in wood and metal, and if these are fitted when building the roof the drip will, of course, be conducted outside the studio.

In view of having to effect repairs, it is a good plan to provide one or more light planks, which can be rested upon the sash-bars so that any part of the roof can be reached in safety. If the bars are of wood, strong screws projecting a couple of inches should be fixed in them so that the plank can rest upon them. Naturally these must be placed a little farther apart than the width of the plank. In the case of iron sash-bars the plank must be supported by ropes—strong sash line will do—thrown over the ridge and secured on the other side of the roof.

There is one little moral to be drawn from all this, and that is to have no more glass in the roof than is actually necessary. I have worked in a studio which was entirely covered with glass, the greater part of which was obscured with brown paint. This answered its purpose, but did not prevent leaks, which occurred to three times the extent which they would have done in a more rationally constructed place. PRACTICUS.

NIGHT PHOTOGRAPHY.

[Perhaps no branch of outdoor photography offers so great a degree of attractiveness as that of outdoor scenes under artificial illumination, particularly to those in large cities where an abundance of subjects of this kind is available. Since the immediately forthcoming season is the best time of year for night photography we take the opportunity of publishing a comprehensive practical article on the subject by an expert in it of long experience, Mr. Robert Dykes, F.R.P.S., formerly senior scientific assistant to the late Sir John Murray, K.C.B., F.R.S., and of the North Sea Fishery Investigations. Part of these notes appeared in a manual on night photography by Mr. Dykes, issued some years ago by Messrs. Dawbarn and Ward, but long out of print. In this final instalment Mr. Dykes describes a method of introducing night and interior subjects into cinematograph films.—Ed. "B.J."]

(Continued from page 503.)

When to stop development is a most serious question, a question often asked, but not easily answered, at least in daylight work. However, one may safely say that a plate is fully developed when the clear margin around the edge due to the rebate of the carrier begins to get discoloured or smoky. The blackness of the high-lights should also be taken into consideration; they must be pretty strong, yet not too strong, or they will print out chalky. Having given half an hour or more for the development of a plate that has been pretty correctly exposed, give it a rinse in a little stronger developer for a moment, wash in water for a minute, and place in the fixing bath. This should be pretty strong, a little stronger perhaps than that used for daylight negatives, as there is considerably more silver to remove. I have no special strength, speaking in a Pickwickian sense, and pop them into a bath made up in a very rough and ready and not too economical way. Thorough fixation is essential, and the plate should not be examined by ordinary light until fixing is complete. I never allow less than fifteen to twenty minutes for this operation; and if the plates are double-coated, not less than thirty to forty minutes.

When a photographic plate is removed from the developer the emulsion is saturated with oxidised and unoxidised developer, caught up or occluded in the emulsion with the reduced silver. Now, if we can imagine a greatly magnified section of the negative in which we can see the actual atoms of silver we would also see this occluded developer as a filament around each silver atom, this envelope of developer holding on by capillarity, much as a film of moisture holds on to one's finger if dipped into water. The brief rinse that one gives to a plate on removal from the developer to the hypo is insufficient to knock this occluded developer out of the emulsion, and negatives of night scenes are so full of unreduced silver that until the hypo has well penetrated the emulsion it is not advisable to turn up the white light. I can hear some photographers pooh-pooing this statement as being rather far-fetched. For ordinary negatives the little harm that might be done would be negligible, but I have obtained a veil before now over an otherwise perfect negative in which the shadows were full of detail, but almost clear glass.

Having fixed our negative, washing is the next and not least

important proceeding; this should be done in perfectly clean running water, so that on removal from the washing tank there are no specks of grit or other particles adhering to the emulsion.

Precautions must be taken in the drying to ensure a perfectly clean negative. Finger marks, dust, scratches, etc., all show up only too plainly when the plate is dry if care has not been taken. There is so much clear gelatine present that dust and marks of any description are far more serious on a "night-scapes" than they would be on a daylight production, particularly if they are required for lantern plate purposes. Stains due to the water trickling down the plate when set up to dry may be prevented by mopping up all the superfluous moisture with a very soft piece of rag, free from fluff, such as an old handkerchief.

Intensification is of no use for this class of work, except perhaps locally to emphasise traces of clouds in a sky. I would strongly advise that a negative be thrown out, and the view re-taken if possible rather than attempt to doctor it up. No amount of intensification will put into a negative what is not there already, and as this treatment affects the whole plate the result is flatness and want of contrast, and without relief and contrast, upon which night views so much depend, our negative is absolutely worthless.

Reduction may be attempted with a certain amount of success, but care has to be taken that it is not carried too far. A reducer should be used that attacks the high-lights first, such as ammonia persulphate. If a ferricyanide reducer such as Farmer's is used the detail in the shadows will be rapidly eaten out. Local reduction is necessary sometimes when an arc lamp shows up too strongly in a view. The mechanical "Globe" metal polish reducer is very handy in such cases if used with a soft artists' stump or a small piece of chamois leather. A great deal may be done with pencil, stump and brush to brighten up the high-lights or soften the shadows.

As to the preservation of the negative, it should be carefully varnished, the plate being well flooded with clear filtered varnish and then thoroughly drained before setting up to dry, for little rills of varnish will print up distinctly. Thin negatives of this description ought to be varnished if they are valued at all, although I may say I do not varnish my own, and as a consequence have lost a goodly number of them through printing stains, etc.

There are many different styles of printing, but the best effects are undoubtedly obtained by printing in pure black and white, for browns, reds, and various other tones hardly lend themselves to "shades of darkness."

First and foremost stands the platinum print, with its beautiful cold black or warmer sepia tones. It is an ideal printing process; at least, thin negatives such as "nightscapes" are ideal printers for this method. Then comes carbon, either by the single transfer process, suitable for some views, such as country scenes, where reversal of the image is of no moment; or by the double transfer process, where it is necessary to have our print the right way about. I prefer black carbon for all classes of night work, but have used blue and even green for moonlight and snow scenes. I would like to warn carbon printers who do not use a safe edge in printing their daylight negatives to do so always in night views, as, owing to their thinness and the rapidity of carbon tissue, they are very quick printers. The gelatine pigment in the shadows as a result frequently becomes so insoluble and tough that it works off the support in development. Many a fine print have I seen get up and walk in this way. Again, I would not recommend boiling over-exposed prints; endeavour to hit the right exposure, and develop up carefully in warm water. Contrasts are so great in night views that printing them in carbon requires considerable skill. The tissue or gelatine pigments perhaps on development won't budge in the shadows except it be in the

lump, and the high-lights, on the contrary, may run so fast owing to under-exposure that they are soon out of sight. Yet the correct exposure once hit—and there is a good amount of latitude, generally speaking, two or three minutes—and you cannot wish for a better or more artistic process.

Coming now to the more workable, less troublesome, and therefore easier methods of printing night views, we have a paper that cannot be equalled for giving platinum-like results—viz., the slow contact paper that permits of getting out all the fine qualities of the negative, and gives rich blacks, soft greys, and pure whites. I prefer it to ordinary bromide paper for night work, as it gives more contrast.

Finally, we have bromide paper of many different makes and of very fine quality either for contact or enlarging purposes. I rarely use it myself for contact work, but use a great deal of it for enlarging. For sharp close grain and pure black and white effects there is nothing like "Wellington" smooth platino-matt; but for artistic effects of breadth and tone Eastman tinted "Royal" is superb.

As to the development of any of these gaslight papers I use amidol, and although I have tried other developers, have not yet come across one to equal it in giving rich velvety black tones. I make it up according to the following formula:—

1 ounce sodium sulphite,
6 grains potassium bromide,
40 grains amidol,
20 ounces water.

As amidol in solution does not keep more than a day or so, it is better to make the developer just before use. The developer must not be diluted, and if, owing to size of paper used, or to using heavy rough papers, it is necessary to soak them in water before development, only use nineteen ounces of water in the above formula. If dilution is resorted to, the blacks obtained will not be black at all, but grey; this may sound a somewhat Irish way of putting it. For this reason also do not leave prints lying too long in the fixing bath; at the same time ensure thorough fixation. Unlike the negative, there is less silver to remove owing to the shadows predominating and the greater amount of reduced silver in the print.

Toning bromides is of no use for night studies, but a yellow colour may be imparted to the high-lights by immersing the worked print in a solution of potassium permanganate about 2 per cent. in strength. This gives an antique and charming effect to the paper, providing it is carefully and properly done, for if too much permanganate be used the print will, after a few days, turn purple and go off colour. Years ago I had the misfortune to exhibit a print treated in this manner, and it had not been on exhibition three days before it went purple in the face—presumably with shame. Needless to say it did not get an award; in fact, many must have wondered what on earth it was.

Choice of mounts and style of frame must be left to everyone's own particular taste, but I have found by experience that dead black borders and black frames set night pictures off to the best advantage.

There are many printing methods that are suitable for night photography, such as "gum-bichromate," the Ozobrome, and the Bromoil pigment processes. Using lamp-black pigments on simple broad nightscapes, one can get some most charming results, in fact, real impressionistic effects, giving that scope for artistic expression that pure photography kills with detail. Whistler's fine appreciation of atmosphere and luminosities enabled him to portray some of the most beautiful after-dark pictures, in which the unnecessary in the way of detail is entirely suppressed. These Whistlerian nocturnes are quite possible to attempt in photography by means of the pigment process of printing to those who have any artistic feeling.

In the preparation of lantern slides of night scenes the slowest plates obtainable should be used, and the reduction carried to the extreme to keep the high-lights from being too obtrusive when thrown on the screen. Some very fine effects may be obtained by toning, the number of different tones available in lantern slide work being considerable, and ranging from warm to cold blacks, blue-blacks, blues, and greens. The carbon pro-

cess yields particularly fine slides for cautious workers, but demands a certain amount of skill and delicacy of handling.

In lantern slide making care must be taken to have perfectly clean negatives, owing to their preponderance of shadow or almost clear glass.

ROBERT DYKES, F.R.P.S.

(To be continued.)

MAPPING FROM AIR PHOTOGRAPHS.

[From the purely photographic standpoint the war-created art or craft of aerial photography can too easily be regarded as having been brought to a high pitch of perfection. It is quite true that by the combined efforts of opticians, camera constructors, and emulsion makers the obstacles which sheer height, the movement of the aeroplane or atmospheric conditions put in the way of obtaining well-defined negatives from the air have been almost completely overcome. Yet that, after all, is only half the battle. An aerial photograph is nothing except in so far as it fulfils a useful purpose. In the important work of map-making the following paper by Lieutenant-Colonel M. N. MacLeod before the Royal Geographical Society is a timely reminder, by an authority, of the distance the aéro-photographie method has still to traverse before it can dispense with the surveyor to supplement or check its results. To anticipate Colonel MacLeod, a general conclusion to which he comes is that "for accurate work we cannot of course dispense with the surveyor altogether, and in hilly country, until we can devise some satisfactory form of stereo-plotter, the air photograph will not help us very much." Other geographers who discussed the paper shared this view, that aéro-photo survey is a branch demanding further research, and that, more at the hands of surveyors and topographers than at those experienced in the purely photographic problems. Such an expression of opinion is not without its significance in reference to the ideas of photographic survey apparently held by the Royal Air Force, to which we recently devoted some attention.—EDS. "B.J."]

(Continued from page 505.)

Before the drawing is reproduced it is always advisable to have a final check made on the ground, to ensure that the interpretation of the photographs has been correctly done. Our method was to take a print from the fair drawing by "Ferrogallic" or "Ordoverax" process, cut this up into pieces of convenient size, and mount on card. The surveyor then took this to the ground and noted on it any errors in "interpretation" or omissions. These latter were not surveyed, but simply marked in roughly in their correct place, being plotted subsequently from the photograph print. Experience showed that this final check, which did not take long, was a very necessary part of the whole process, even when the plotting had been done by very experienced men. When, owing to the maps being of parts of enemy country, this check was impossible, its place could be taken to some extent by comparing the map with "oblique" photographs also taken from aeroplanes. These "obliques" were taken from a low altitude, and give a sort of panoramic view, on which vertical objects such as trees, buildings, and churches, etc., show up very much more clearly than on the ordinary vertical photographs. Unfortunately, they were rather difficult and dangerous to take, and we could not count on obtaining them, at any rate from the most favourable positions.

The time taken in adjusting the enlarging camera and apparatus varied with the amount of distortion of the photograph, but averaged about five minutes. If the photograph is very much distorted it is difficult to get the image in focus all over the board, and this method of plotting is therefore not very suitable for very tilted photographs.² We rarely used tilted photographs for plotting work, but it would appear that the Germans, owing to their inferiority in the air, were compelled to place considerable reliance on them, and they appear to have used a different method of plotting, which I will describe later on. Before doing this I will say a little more about our own methods.

Having completed the map as described above, we had to keep it up to date by plotting on it all new trenches, battery positions, and the like which appeared on subsequent photographs. It was rarely necessary to use the enlarging lantern for this purpose, as, having once completed the map, one could always obtain a large number of suitable fixed points on any photograph and plot with sufficient accuracy and speed with the proportional compass. Occasionally, however, it is desirable to plot a point with greater precision; such points may be points required to enable another photograph to be plotted or points required by the artillery for use as a "datum" or "zero" point for registering or observing their fire. For such

points the method known as the "four-point method" is often most suitable. It is as follows (see Figs 1a and 1b):

Fig. 1a.

Assuming four fixed points can be identified on the photograph, then using one point as apex, join it to the other three both on

Fig. 1b.

the photograph and on the map. On the photograph draw a line from this apex to the point to be plotted, then, taking a slip of

² See previous footnote.

paper with a straight edge, lay it across these four lines, roughly at right angles to the centre one, and "tick" off on the edge of the slip the points where each of the lines cut it. Transfer the slip then to the map and lay it across the corresponding lines on the map, moving it about until the three "ticks" due to the "fixed" rays on the photograph come over the three rays ruled on the map. Now mark the map at the tick corresponding to the ray to the point to be plotted. A line joining this mark to the apex passes through the true position of the point on the map. Repeat the process, using another apex to obtain a second ray, whose intersection with the first gives the position of the point. Using a third apex, one gets a third confirming ray, which should also pass through the point and gives a check on the accuracy of the plotting.

These methods are theoretically accurate, whatever the inclination of the photograph, provided the points lie in the same plane, and in practice, when this is the case, the three rays obtained in this way give a perfect trisection. The proof depends on the fact that the anharmonic ratios of four points on a straight line are not altered by a perspective.

When instead of one point only a number of points have to be plotted by this method, it is best to stick the photograph down on a piece of paper and rule in the rays from the apex, produce them beyond the edge of the photograph and rule in the transverse line. Cut or fold the paper along this line, and, having ruled in the corresponding rays from the apex on the map, place the photograph over it, face upwards, and turn it about till the transverse line comes in its correct position, when it is ruled in on till the transverse line comes in its correct position, when it is ruled in on the map also.

The transverse lines are then scaled, and plotting can proceed without ruling further rays on the photograph by simply laying a straight-edge from the apex to the point to be plotted, and noting the scale, reading where it cuts the transverse line. The corresponding ray is plotted from this scale reading on the map.

I will now go on to describe some of the methods which appear to have been used by the Germans. The most useful of these is

Fig. 2.

based on the principles of perspective in freehand drawing, and may be described as "perspective plotting" (see Fig. 2).

Suppose ABCD to be a square on the ground. In a photograph taken truly vertical this will appear as a square, but on a tilted photograph it will be seen in perspective and appear as a quadrilateral, *abcd*, of which the sides *ba* and *dc* converge to a "vanishing" point on the left, and *ca* and *db* to another "vanishing" point on the right.

The plotted position of O will be given by joining the diagonals of this figure and the positions of P, Q, R, S, by drawing lines from the two "vanishing" points through O. By joining PQ, PS, QR, SR, we can still further subdivide the true square and its perspective view and obtain further corresponding points on map and photograph, and this process can be continued indefinitely. The principle of perspective here involved is applicable of course to any figure; the square is selected for an example, as it is the easiest in which to follow the connection between the original and the perspective view.

To plot from a photograph by this method it is necessary to select a quadrilateral figure formed by four fixed points on the map and the corresponding figure on the photograph (Fig. 3).

Fig. 3.

Join up the sides and diagonals and produce the converging sides to meet, both on the map and on the photograph. Then from each of the "converging" points draw a line through the intersection of the diagonals to cut the two opposite sides of the quadrilateral. This sub-divides each quadrilateral into four corresponding smaller quadrilaterals of which the diagonals are again ruled in, and the process carried on till finally both map and photograph are covered with a grid of lines joining points which correctly correspond to each other. When this grid is sufficiently small it is easy to sketch in by eye all the intervening detail on the photograph by its relation to the grid-lines. This method is useful for dealing with considerably tilted and distorted photographs, but is naturally not so satisfactory as our method of rectifying the print in a camera when the latter is possible. We never had occasion to use it, as, for mapping work at least, we were almost always able to obtain photographs which were very nearly vertical.

Tilted photographs are always objectionable for plotting by this or any other method, for the reason that differences of level on the ground introduce large errors; they can only be used with safety in flat country.

If five fixed points are available, plotting may be done in a similar way without the use of the auxiliary points obtained by producing the sides of the figure, by simply joining up each point to the three points opposite to it, and then from each point drawing a line through the intersection of the diagonals drawn between the other four points and obtaining two corresponding grids in this way.

Fig. 4a.

It will have been observed in all the foregoing methods of plotting that at least four fixed points are required.

At first sight it might be seen that three points should be sufficient, and it may therefore be as well to consider at this stage the geometry of the plotting to see why four and not three points are necessary.

In Fig. 4a, suppose AB be two fixed points on the ground and

Fig. 4b.

C a point intermediate between them, *a, b, c* being the corresponding points as they appear on the photographic plate. Now, if on the plate *c* is exactly half-way between *a* and *b*, the line *CL* will bisect the angles *aLb* and *ALB*. The point *C* on the ground will not, however, be exactly half way between *A* and *B* unless the photograph is truly vertical, that is unless $AL=BL$.

Suppose, then, we have our air photograph *acb* and wish to plot the point *C* in its true position between *a* and *b*; we wish to plot it in the position *C'* where *A'B'*, the correct map length of *AB*, is parallel to *AB*.

What we actually do with the photograph by means of the camera lucida or the enlarging lantern is shown in Fig. 4b.

We throw an image on to a board $A_1C_1B_1$ whose dimensions we can regulate by moving the board and the focus until $A_1B_1 = A'B'$. We can, however, also alter the length of any line in the image by tilting the board. When we do not know the angle at which the photograph was taken, how are we to know which means to adopt?

Obviously we do not know which to adopt unless we have other data. If we know the ratio *AC* to *CB* we evidently can get the adjustment along the line *AB* correct by moving and tilting the board till A_1B_1 is its correct length and A_1C_1 and B_1C_1 are also correct, that is into the position $A_2C_2B_2$, which is the only position which will have all the elements correct. To adjust in any direction in this way we therefore require three points. To adjust the whole photograph, which is in two dimensions, we must, however, adjust in two directions at right angles to each other, and we therefore require three points in each of two directions. One of these points can be a common point used for each direction, making five fixed points. If, however, we start with a quadrilateral of four points, the intersection of its diagonals gives us a fifth on both map and photograph, and we see therefore that four independently fixed points is the minimum number which give sufficient data in themselves for accurate plotting.

It may happen, however, that four independently fixed points cannot be obtained. Should this be the case, it is necessary to supplement the intrinsic data on the photograph from other sources. If the focal length of the lens used is known, a photograph can be accurately plotted from three points only, by a method evolved by the Germans and known by them as Hugerstoff's Pyramid Method.

This method requires a complicated geometric construction for plotting of each point, and I am thankful to say I have never had occasion to use it. It is as follows:—

If we draw in the rays from three points on the ground through the lens of the camera to their images on the photographic plate, we obtain two pyramids of equal apex (as in Fig. 5).

If we can determine this apex, we can reconstruct the two pyramids, because we know the lengths of the sides forming the bases of each, namely, *ABC*, formed by the three fixed points

on the ground, and *a, b, c*, the corresponding points on the photograph.

If we know the focal length of the lens used and the centre of projection, we have all the elements necessary to reconstruct the pyramid within the camera, and from it determine the apex, after which we can proceed to reconstruct the other or "map" pyramid,

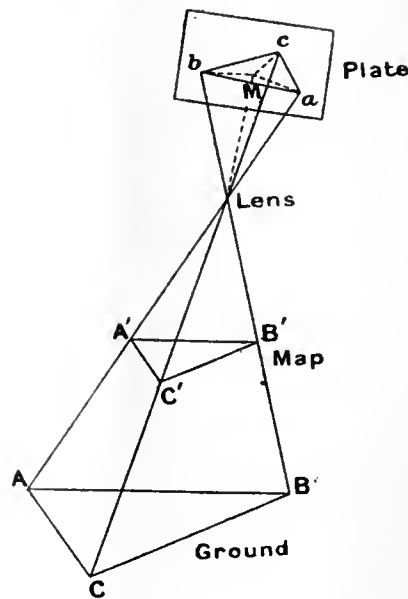

Fig. 5.

a section of which $A'B'C'$ parallel to the ground such that $A'B'$ is the map length of *AB* gives us the representation of the ground on the map.

The focal length of the lens being known, the centre of projection is obtained nearly enough by the intersection *M* of the lines joining the corners of the negative, and the lengths *aL*, *bL*, and *cL* are obtained from the right-angled triangles *aLM*, *bLM*, and *cLM*. This is done graphically as follows (see Fig. 6):—

Fig. 6.

Join *ABC* on the photograph and the corners of the print to find *M*. Draw a line O_1M_1 equal to the focal length of the lens, and a line at right angles to it, along which step off MC_1 , MA_1 , MB_1 , equal to *MA*, *MB*, *MC*. O_1A_1 , O_1B_1 , and O_1C_1 are therefore the sides *LA*, *LB*, and *LC* of the camera pyramid.

We can now proceed to reconstruct this pyramid on paper. To do this we must imagine the pyramid out down the side *LC*, the adjacent sides opened out flat and the base folded down till all faces lie in the same plane.

The pyramid is reconstructed on this plane surface as follows (see Fig. 7):—

Fig. 7.

Draw a line O_2A_1 equal to O_1A_1 . Then with O_2 as centre and O_2B_1 as radius, draw an arc of a circle, and from A_1 as centre and ab as radius draw another arc cutting the first in B_1 . $O_2A_1B_1$ is the face of the pyramid *lab*. Next draw in the base $A_2B_2C_2$, which is the triangle *abc* on the photograph. Then with O_2 as centre and radius O_2C_1 , describe two arcs, one on each side of the face $O_2A_1B_1$; with A_1 as centre and A_1C_1 (or *ac*) as radius describe an arc cutting one of these in C_1 , and with B_1 as centre and B_1C_1 as radius another arc cutting the other in C_1 . Join O_2C_1 and O_1C_1 ; then $O_2C_1A_1$ and $O_2C_1B_1$ are the other two faces of the pyramid, which is now completely reconstructed.

We can now proceed to reconstruct the map pyramid $L_2A'B'C'$. We have already got the apex drawn, since it is the same as the apex of the camera pyramid, and we require to draw the base $A'B'C'$. The best way to do this is to draw AB on tracing-paper, and on this trace draw an arc with centre A' and radius $A'C'$, and another arc with centre B' and radius $B'C'$. The intersection of these will obviously give the position of C' with respect to $A'B'$ or the base of the required pyramid, and we require to place this base correctly on the face $O_2A_1B_1$. This is done by laying the trace over the drawing and turning it about till A' and B' lie on the lines O_2A_1 and O_2B_1 , respectively, and the two arcs cut the sides O_2C_1 and O_2C_2 at equal distances from O_2 . In this position the points are pricked through on to the drawing and give the positions $A'B'C'$ on the map pyramid, the positions of C on the two sides being lettered C'_1 and C'_2 .

Individual points, whether lying within or without the triangle ABC , can now be plotted as follows:—

Let P be such a point on the photograph. Join A_2P and B_2P and produce these lines to meet the opposite sides, produced, if necessary, at u and t respectively. Then with B_2 as centre and radius bu draw an arc cutting the side of the camera pyramid B_2C_2 at u_1 , and with A_2 as centre and at as radius draw an arc cutting the side A_2C_2 at t_1 . Join O_2t_1 and O_2u_1 , cutting $A'C'_1$ and $B'C'_1$ at t_2 and u_2 , respectively. Then with centre A_1 and radius A_1t_2 and centre B_1 and radius B_1u_2 , draw arcs cutting AC and $B'C'$ at t' and u' respectively. Join $A'u'$ and $B't'$, and the intersection of these two lines gives p , the plotted position of P on the base of the map pyramid, that is, on the map.

This method of plotting is so slow and laborious that, having plotted a fourth point in this way, it is probably better and quicker to plot the rest of the photograph by one of the four-point methods already described.

The Germans apparently made use of several other methods

which are extensions of or modifications of these two, and probably also photographic methods very similar to our own. Captured documents also mention a "stereo-plotter," but I do not think we have any information as to exactly what this apparatus is or how much it was used.

To turn now to the use of air photographs for showing up the shape of the ground and determining vertical relief. Though "stereoscopic" examination of air photographs has been employed for some time, certainly more than two years, I know of no instrument or apparatus, such as the stereo-comparator used in panoramic photograph surveying, which has yet been devised for accurately plotting vertical heights. I myself devoted a good deal of attention to the study of aeroplane photographs in relation to contouring, and found that though it was often possible to obtain great help from them, such help, however, could not be reduced to terms of exact measurement of height or anything in the nature of plotting. When the slopes are steep, as, for example, in the dunes along the coast or along the Mont des Cats-Kemmel Ridge, the stereoscopic use of air photographs often shows the shape of the ground very well, but to transfer the view thus obtained to the map in the form of contours, without the help of some apparatus, is more in the nature of art than exact science.

With good stereoscopic photographs in such country, it is not difficult to pick out the tops of the ridges, bottoms of the valleys, and the "peaks," which can be marked on the photographs and plotted in the usual way. This will give a very good general idea of the shape of the ground, but one cannot get the absolute height in this way or say which of two "peaks" or ridges some distance apart is the higher, and it is necessary, therefore, for drawing contours, as opposed to form-lines only, to observe as many heights as possible with a theodolite or clinometer.

On the Mont des Cats we were able to observe a number of such heights, and the resulting contours, though by no means perfect, were a great improvement on anything which had existed before; subsequent examination showed that they gave a very fair idea of the shape of the ground, and were rarely seriously inaccurate in absolute height. Apart from stereoscopic photographs, however, air photographs often give useful information as to the hydrography. In the chalk region of the Somme Valley "hanging woods" growing on the steep sides of a valley, of which "Caterpillar Wood" is a well-known and characteristic example, give a good idea of the trend of the valley bottom. In the Ypres area the valley bottoms are often revealed by the "lush" meadows, which can usually be picked out on the photographs. Tillage lines and boundaries of fields generally bear some relation to slope and drainage, which can sometimes be deduced from them.

All these points, however, are no more than indications; and though care, judgment, and experience in observing and applying them often results in a surprisingly good approximation, it cannot be said that it is yet possible to rely on an air photograph alone for anything like accurate contouring.

The contouring of maps in France interested me very much, and I put in a lot of time trying to elaborate our scanty data by examination of air photographs and other material. My printing officer used to tell me that whenever he had to print a new edition of a map I produced a new "design" for the contours. I am afraid that my "designs," in spite of the time spent on them, often came in for severe criticism. Nevertheless I must own that where the ground was suitable, and it had been possible to give the matter sufficient consideration, I thought the results distinctly good. Unfortunately the work took so long, and required so much care and caution in drawing conclusions, that time did not permit of detailed examination of more than very limited areas.

It should be remembered that in France we were working under war conditions and at high pressure, and had to do the best we could with available data and apparatus in the available time. Many of our maps could have been improved as regards the contouring if we had had more time to give to them. In using air photographs for mapping work in peace time conditions will be very much easier, and I don't doubt that our systems and methods can be greatly developed and improved, both as to the nature of the photographs and the methods of using them. The Germans,

As I have said, almost certainly employed a mechanical device for determining the amount of tilt of the camera, and it certainly does not seem to be beyond the bounds of possibility to devise means of determining the scale of a photograph with fair accuracy without the necessity of providing an elaborate framework of points fixed on the ground.

In peace time a machine need not carry an observer, machine guns, or ammunition, and more space and weight will be available to devote to improving the size and type of camera used. Very little further development, in fact, is required to give us the power, not only of preparing complete and accurate large-scale maps of civilised and highly developed regions, but also of obtaining reasonably accurate maps of unexplored regions, at present untouched and inaccessible to anyone but the explorer.

In civilised countries it is obvious that detailed survey by air photograph is a method which will give the minimum of inconvenience to the occupiers of the ground—we shall not need to invade their premises at all, while its accuracy will probably be greater than that now attained by any but the most expensive methods.

For accurate work we cannot, of course, dispense with the surveyor altogether, and in hilly country, until we can devise some satisfactory form of stereo-plotter, the air photograph will not help us very much. There does not, however, seem to be anything to prevent us making such an instrument, and when this is done it should be possible to map steep hilly regions, at present difficult to survey on account of the difficulty of getting about in them, very cheaply indeed. When it is not possible to send a surveyor over the ground to check the interpretation of the photographs, his place can be filled to some extent by the examination of "oblique" photographs taken from aeroplanes at suitable altitudes.

One may safely sum up the situation by saying that the aeroplane is already a valuable instrument for both exploration and accurate survey in flat country, and that it should not be long before its application will be almost universal, and one may venture to predict that in survey, as in many other matters, the Great War will mark the beginning of a new era.

M. N. MACLEOD, D.S.O., Lieut.-Col., R.E.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, SEPTEMBER 6.

North Middlesex Photographic Society.—Outing to the Charterhouse.
Hackney Photographic Society.—Outing to Coulsden.

TUESDAY, SEPTEMBER 9.

Hackney Photographic Society.—"Carbon Demonstration," W. Rawlings.

THURSDAY, SEPTEMBER 11.

Hackney Photographic Society.—Outing to Strand-on-the-Green.
Hammersmith (Hampshire House) Photographic Society. "The Minor Sculptures of Our Churches," A. Gardner.

CROYDON CAMERA CLUB.

At the conclusion of a recent demonstration by Mr. Cecil Smyth on the making of light-filters, a member, acting of genial malice aforethought, suggested a second evening on their application to practical orthochromatism. Had Mr. Smyth realised the deadly civil war waged in the past between the members he might well have hesitated, a war recalling many bright engagements, when quarter was neither asked nor given. It eventually died down owing to sheer inanition, since when the subject has been tacitly taboo, each side respectively realising, if not openly admitting, that panchromatic and ordinary plates each have their uses and relative advantages.

Of course, there is still in the world the well-meaning enthusiast, who, possibly with limited experience, is partial to lecturing the man who does the work, familiar with all the tools available, and who knows quite well the ones he prefers for the job. Hence ordinary plates still flourish, and are still used for portraiture.

From an *ex cathedra* point of view this is sad, but the sinners mourn not, and on occasion have even been known to snigger and make disrespectful allusions to the education of grandmothers in connection with the consumption of eggs.

Mr. Smyth's lecture resolved itself into a clear "blackboard" description of the action of light-filters, selective and compensating, three-colour work also being touched upon. He then resumed his seat without even a button off a glove having been thrown down as a challenge, which was distinctly disappointing. However, by specious compliments he was prevailed upon to continue, and "practical panchromatism" entered the ring. "How is it possible to render adequately a Devonshire scene with red cliffs, vivid green foliage, blue skies and cows, etc., other than by a screened panchromatic plate?" he asked, a question admirably adapted for starting a Canadian frolic; but, alas! none arose on this particular point. Miserable to relate, habitual users of "ordinary" brands weakly admitted that the panchromatic often scored heavily in pictorial photography, and so crumbled to dust a once nutritive bone of contention. The club is not what it was, Sellors notwithstanding.

Nevertheless, an animated discussion followed, marked by an excellent contribution by Mr. Cavendish Morton, who preaches as well as he practises, which is saying a good deal. By easy stages he slid off the subject into that morass known as "diffusion of focus," introducing Durer and Holbein as apostles of the opposite, and then dealt with various problems relating to portraiture. Panchromatic plates and filters made no appeal to him in this branch, *nuances* and other factors being far more important. Mr. E. A. Salt denied that any normal filter existed with "*nuance*" absorption, and said he always appreciated the inherent humour of diagrams of spectral cuts. He well remembered a late member and rabid panchromatist who experimented largely with a spectroscopically adjusted red filter in landscape work. The greens were very nicely rendered indeed, even if they were not truthful transcriptions. Mr. Hunter observed he had known similar cases. Mr. Cavendish Morton agreed. Some might remember a three-colour portrait shown by him years ago at a R.P.S. exhibition. The three negatives were extraordinarily alike, and each would have rendered a good monochrome print. On the psychological side the president, Mr. J. Keane, was understood to say he preferred seeing red; certainly the reds were more important than other colours in the sense of arresting attention. This was illustrated by red roses, pillar-boxes, etc. Mr. H. King had used panchromatic plates in his studio on difficult subjects with satisfaction, but he had found freckles appeared more strongly on them than on fast "ordinary" brands. Next, please!

The evening terminated with a hearty vote of thanks to the lecturer, and a bitter complaint by a member that since the war selective absorption had been almost an unknown factor in the club. Only one brand of a certain transparent medium was obtainable, and that of miserable quality. Throughout the proceedings a distinguished visitor, Mr. J. S. Hudson (the hon. sec. of the Bourne-mouth Club), sat an interested and somewhat amazed spectator, especially when Mr. Cavendish Morton attempted to spank the "office boy," who had made rude remarks about "Art."

FORTHCOMING EXHIBITIONS.

September 13 to October 11.—London Salon of Photography.
Hon. sec., 5a, Pall Mall East, London, W.C.1.

October 13 to November 29.—Royal Photographic Society.—
Entries close September 19 (carrier), September 20 (hand).
Secretary, J. McIntosh, 35, Russell Square, W.C.1.

IMPORTATION OF PAPER.—In accordance with the recent decision of the Government, a general authority has been issued to the Customs authorities under which all articles covered by the regulation as to the importation of paper will be admitted into this country without licence as from August 29. The Paper Import Restrictions Department at 23, Buckingham Gate, S.W.1, will close on September 6, and further communications on the subject should be addressed to the Department of Import Restrictions, 22, Carlisle Place, S.W.1.

Commercial & Legal Intelligence.

LEGAL NOTICES.—A first and final dividend of 4s. in the £ has been declared in the estate of Harry Saville Thorne, chemist and photographer, 5, Finkle Street, Selby, late 93, Sackville Street, Barnsley afterwards, 5, Finkle Street, and 26, Finkle Street, Selby, all in Yorkshire. This dividend is obtainable at the office of Geo. Hy. L. Volans, 2, Albion Place, Leeds.

NEW COMPANIES.

SELBY CHEMICAL Co., LTD.—Registered with a capital of £55,000 in £1 shares. Objects: To carry on the business of chemical manufacturers, importers, exporters, buyers, and sellers of heavy and fine chemicals, photographic and other preparations. The subscribers (each with one share) are: C. G. Mayfield, Temple Buildings, Bowalley Lane, Hull, solicitor, and G. H. Sowards, 131, Victoria Avenue Hull, solicitor's managing clerk. Table "A" mainly applies. Qualification £100. Registered office: Holme Works, Holme Lane, Selby, E. Yorks. Private company.

N. L. SCOTT AND Co., LTD.—Registered August 22. Capital, £10,000 in £1 shares. To take over the business of manufacturers of cinematograph film stock and photographic papers carried on at 3, Pantras Lane, E.C., as "N. L. Scott and Co." The subscribers (each with one share) are:—H. G. Yorke, 31, Caversham Avenue, Palmer's Green, company secretary, and T. W. Skinner, 8, Water Lane, Ludgate Hill, E.C.4, clerk to Greenhill and Sons, Ltd. The directors are to be appointed by the subscribers. Registered office: 8, Water Lane, Ludgate Hill, E.C.4. Private company.

R. WHITE'S PHOTOGRAPHIC Co., LTD.—Registered with a capital of £500 in £1 shares. Objects: To take over the business carried on by R. White at Hill Lane, Macclesfield, Cheshire, and to carry on the business of photographers, enlargers, picture framers, dealers in photographic plates, papers, and all general photographic requisites, etc. The subscribers (each with one share) are:—B. Goodman, 55a, Great Ducie Street, Manchester, photographer, and R. White, 5, Park Street, Macclesfield, photographer. The permanent directors are B. Goodman (chairman) and R. White (managing director). Qualification: £50. Registered office: 40, Hill Lane, Macclesfield. Private company.

News and Notes.

NATIONAL PHYSICAL LABORATORY.—The Lord President of the Council has appointed Professor Joseph Ernest Petavel, D.Sc., F.R.S., M.I.Mech.E., etc., to be Director of the National Physical Laboratory in succession to Sir Richard Glazebrook, C.B., F.R.S., who retires on reaching the age limit on September 18 next.

PRESS PHOTOGRAPHIC AGENCY.—In recently mentioning this Press agency we gave its address as 170, Fleet Street, from which premises, however the Press Photographic Agency moved some two months ago to larger quarters at 3, Johnson's Court, Fleet Street, E.C.3.

PRESENTATION TO MR. A. R. OSBORNE.—A representative gathering of the Dublin photographic trade was held at Messrs. Robinson's, Westmoreland Street, for the purpose of presenting an address and testimonial to Mr. A. R. Osborne, late Irish manager of Messrs. Kodak, Ltd. Mr. Hemenstall presided, and in a witty and eloquent speech proposed the health of Mr. Osborne. Mr. J. E. Beehan, who was assisted by Mr. McCrae, who had acted as secretary, read the address, and the chairman presented Mr. Osborne with a case of Treasury notes. Tributes to the good qualities of Mr. Osborne were paid by Mr. Glenn, Mr. W. McCrae, and others. Mr. Osborne made a suitable reply.

SURPLUS AERIAL PHOTOGRAPHIC SUPPLIES.—The Board of Disposal of surplus Government property have now available for distribution itemised lists of photographic material, the bulk of which necessarily has come from the Photographic Section of the Royal Air Force. The lists specify a considerable number of aerial cameras, about 460,

of which 132 are of the C type, 5 x 4 size without lenses, and 189 the L type, also 5 x 4 size, with lenses. The most important item, however, in the apparatus section is the anastigmat and other "aerial and ground" lenses to the number of 340, and of assorted focal lengths, 5, 6, 8, 10, 11, 12, 14, 16, 18, 20, 25 and 30 inches. These 340 lenses are listed as one item, which fact, it may be hoped, is not intended to signify that they are to be disposed of in a single lot. Lenses are the articles of greatest utility at the present time apart from aerial photography, and their disposal in a single block necessarily eliminates the direct purchaser and passes the distribution of the instruments through a further channel, where necessarily a profit has to be taken. Other apparatus includes cameras for aerial gunnery, enlargers, optical lanterns, and a very great number of miscellaneous accessories such as dishes, printing frames, light-filters, developing tanks, dark-room lamps, and optical lanterns. A large part of the list is taken up by itemised lists of dry-plates and bromide papers for disposal. The bromide papers (which include also gas-light) show an astonishing variety of brand and grade. They include the following, each item representing a certain number of gross packets ranging in size from 5 x 4 to 25 x 25 inches:—

Criterion contrasty	Kodak special matt velvet
— gaelight	Kosmos
— Non-stress silky	Wellington carbon
— Normal	— Enammo contrasty white
— Special	— platino-matt smooth
Griffins' snow-white glossy	— rough
Illingworth contrasty R.A.F.	— S.C.P.
— glossy mauve	— S.C.P. enammo mauve
— glossy special	— slow contrasty glossy
— Ivory matt	— slow contrasty matt
Kodak Nikko mauve	Velox special
— platino-matt	— Vigorous carbon
— rough white	— Vigorous glossy

Particulars and forms of tender for these photographic goods are obtainable from the Surplus Government Property Disposal Board, Miscellaneous Stores Section, Caxton House, Tothill Street, Westminster, S.W.1.

SCIENTIFIC AND INDUSTRIAL RESEARCH.—The report of the Committee of the Privy Council which has made itself responsible for the organisation of research in a number of industries, has just been issued, and is obtainable from H.M. Stationery Office, Kingsway, W.C.2, or from the customary agents for Parliamentary papers in Manchester, Cardiff, Edinburgh, and Dublin, price 6d. The report consists of an extended survey of industrial research in this country and in other parts of the Empire. It outlines certain proposed programme such as the "Records Bureau," to which we made reference last week. It contains a list of established research associations, of which the British Photographic Research Association was the first, and of the various sub-committees engaged in the examination of industrial questions. In that part of the report dealing with the formation and development of research associations special reference is made to the body representing the photographic trade, namely in the following passage:—"The British Photographic Research Association has completed its preliminary survey of the field of research, and has drafted a valuable and comprehensive scheme of work, which we think other research associations might usefully consult as an example of the way in which their plans of campaign may be attractively presented to their members. The Research Association has decided to attack the problems which confront it not only by the empirical methods which have brought the photographic industry the success it has already achieved, but also by investigating fundamental principles. This is a long-sighted view which we welcome. A number of investigations of direct industrial application have already been completed. For instance, useful experiments have been conducted on gelatine and on photographic emulsions, and a successful process which it is intended to patent, has been discovered by which it is possible to stain wood black or grey right through. This process is expected to be quite economical and suitable for use on a large scale; and it is interesting to note that the research was guided by a knowledge of the methods used in dyeing cotton. The association also makes a point of publishing all results of research which are likely to be of general interest and not of immediate use for application to specific problems of the industry."

Correspondence.

. Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

. We do not undertake responsibility for the opinions expressed by our correspondents.

THE PHOTOGRAPHIC SECTION OF THE R.A.F.

To the Editors.

Gentlemen,—I have read your remarks of August 22 concerning the peace-time Photographic Section of the R.A.F. with great interest and sympathy. With much that you say I am in total agreement, but I feel that certain other of your suggestions are hardly justified.

On good authority I learn that demobilisation of the photographers of the R.A.F. has progressed so far and so rapidly that lack of men is greatly retarding much necessary work.

Again, advertisements of the sale of photographic surplus equipment have already appeared in the Press, and a great amount of material has already been sold.

Further, for military training, aeroplanes must fly and pilots must be taught to take aerial photographs. Why should not both be employed in taking photographs that will be of benefit to the country? The solution of town-planning and other reconstruction problems would be helped by good up-to-date photographic records, which would be produced more cheaply under the above scheme than by private enterprise.

In connection with aerial photographic survey, experimental work must necessarily be done under peace conditions to determine, among other things, the questions of its cost in comparison with the present survey methods.

The Ordnance Survey maps of this country, excellent as they are, are in very many instances quite twenty years out of date. R.A.F. aerial photographs could speedily be used to correct them, and few people ever suggest that the Ordnance Survey maps should be made by private enterprise.

The zeal of the photographic officers of the R.A.F. to do their work thoroughly does not, I think, indicate that they have the least desire either to burden the taxpayer unnecessarily or to trespass upon the legitimate ground of civilian effort.

Yours faithfully,

F. SEYTON SCOTT.

Arranging the Picture Directly.

It is when we come to portraiture that the greatest advantage of the direct view of the subject is most appreciated (says E. R. Hollins in "Amateur Photographer" for September 3). Before even the sitter is asked to take his place, or while in the act of doing so, the photographer should visualise the general arrangement of what he means to secure. He should so accustom himself to this preliminary conception that when the time comes to do the work he can ask his subject right away to adopt the position he requires. The mere fact that he can do so with quiet confidence will help to put his sitter at his ease, a result which will be intensified when the sitter finds that he is not asked to adopt first this position and then that while the photographer gropes for what he wants. Then when looking directly at his subject he sees it as it should be, he may introduce the camera, quickly make sure that his mental picture is included on the ground glass, focus, and expose before the model has had time to acquire any stiffness or feeling of ennui.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

R. M.—There are two Retail Businesses Licensing Orders, one of February, 1918, and the other of May 30, 1919. We believe there is some confusion about them, but at any rate it is clear that if your business was established on June 15 of this year you require a licence for it.

J. M. K.—The best method for toning to "sanguine" is to tone prints by the ordinary so-called sulphide process, that is bleach in a bath of ferricyanide and bromide and darken in a sulphide bath. The sepia or sulphide-toned prints are then further toned in an ordinary gold and sulphocyanide bath, as used for the toning of print-out gelatine paper. One of the best methods we know for removing yellow stain from bromide prints is to employ the iodine-cyanide reducer made very weak and used cautiously.

J. H.—(1) Try warming outside of bottle neck all round over a gas flame, and then tapping the stopper, preferably with a bit of stout glass tube; at any rate, with an article of glass. (2) Not as good. Nigrescine from Harrington Bros., Oliver's Yard, City Road, E.C.1. (3) No material harm for black prints, although it is best to keep to the maker's formula: for sepias by sulphide toning, too strong developer is a cause of poor tones, by causing a less thorough development of the black print.

SUMMARY

In a leading article we give some advice on the ordering of half-tone and line blocks, pointing out how some economy can be effected by grouping originals together and giving a hint on getting the engraver to supply facsimile reproductions of originals which contain more or less delicate tones. (P. 526.)

In the concluding instalment of his article on night photography Mr. Robert Dykes, F.R.P.S., describes the method devised by himself for introducing interior and night subjects into cinema films so as to sustain the effect of movement. (P. 528.)

In his article this week "Practicus" deals with the alternative systems, of blinds and curtains, for the control of the light in a studio. (P. 530.)

An Australian writer, Mr. W. H. Moffitt, has sought to simplify the working instructions for the Osborne process. He gives formulae for making the pigmenting and acid bath. (P. 531.)

The Professional Photographers' Association is advertising for a paid secretary. (P. 525.)

An exhibition of "straight photographs" by Mr. Ward Muir is now being held by the London Camera Club. (P. 535.)

Two inventions in colour photography, for which large claims are made, have obtained some publicity in the daily Press. (P. 537.)

Apparatus for aerial stereoscopic photography and a modified composition for the true-to-scale process figure under "Patent News" (P. 535.)

A correspondent, Mr. A. Palfreyman, strongly objects to criticisms of the reflex camera on the ground of its unsuitability for use at eye level, and describes and illustrates the special hood, fitted with a mirror, which he employs for using the reflex in this position. (P. 538.)

Mr. Harold Baker expresses his good opinion of the Bellini reducer for negatives and prints. (P. 539.)

The Colour Laboratory of the United States Bureau of Chemistry has prepared a new developer, paranino-carvacrol, made from cymene. (P. 534.)

Professor J. W. Nicholson, F.R.S., has recently described a photographic method for the measurement of the intensity of spectrum lines. (P. 533.)

Methods which have been used for producing, by optical means, a background (of any subject) in a portrait are the subject of a paragraph on page 525.

The present time—namely, a few weeks before the termination of "daylight saving"—is a fitting one in which to carry out any renovation of artificial-light equipment. (P. 526.)

Two reducers serve well for remedying over-printed and gold-toned P.O.P. prints. They are ammonium persulphate and the mixture of ferricyanide and sulphocyanide known as Haddon's reducer. (P. 526.)

EX-CATHEDRA.

Paid Secretary for the P.P.A.

The announcement which appears on another page under "Situations Vacant" signifies a policy on the part of the Professional Photographers' Association which perhaps many members of the P.P.A. have anticipated. It is now proposed to appoint a paid secretary of the Association to undertake routine business, to produce the P.P.A. Circular, and to carry out the organisation of the annual congress. Mr. S. H. Fry, who undertook the duties of honorary secretary some few months ago, did so, it will be remembered, on the understanding that he should occupy that office only for a twelve-month; so that it may be assumed that the step now being taken is for the purpose of stabilising the secretarial management of the P.P.A. and of preparing the Association for such developments as the future may have in store for it. It is obvious from the wording of the Association's advertisement that a professional photographer who is, or has been, in business for himself is required, and it can be understood that the result of the appointment will be watched with no little interest by those who take a long view of the influence of the Association in the photographic world. For while the policy of the P.P.A. will continue to be that of the council, a large responsibility for its effective administration, and even for the lines along which it shall work, will rest with the secretary.

Natural

Backgrounds. Our paragraph of August 22 on Mr. Elwin Neume's invention has brought us one or two inquiries as to the methods employed by previous inventors of systems for producing the same description of effect. Without wishing to suggest that there is anything in common between these and that of Mr. Neume's, we may say briefly what they are, or rather were, for, so far as we know, they have never come into regular use. The method of Tilley consisted in mounting a positive transparency of the background subject in a hinged frame placed within the camera so that, by an outside lever, it could be pressed against the plate. The sitter was first photographed against a dead black background under the ordinary lighting, the positive transparency in the camera being turned down out of the way. Then, without any movement of the sitter, the black background was drawn up and a white translucent one let down. At the same time the lighting previously used was cut off and the white background illuminated from behind. The background transparency in the camera was also raised to bring it close in front of the plate. On a second exposure being made under these conditions the background was impressed upon the plate by contact printing except where the projected dark silhouette, so to speak, of the sitter formed an unilluminated area in the focal plane. The outline of the sitter, in other words, was caused to form a kind of optical mask for cutting out just that portion of the background

which otherwise would have overrun the image of the sitter made at the first exposure. Dischner's method was almost identical with this except that it was better adapted to artificial illumination, and he, of course, used dry-plates, whereas Tilley's process was carried out under the handicap of the wet-collodion plate. The method of Sontag, to which we also referred, was much simpler, and consisted merely in placing the sitter against a translucent screen on to which the background was projected by means of an optical lantern placed behind it. The feature specially claimed for Sontag's invention consisted in making the translucent screen of non-actinic colour.

* * *

For Artificial Light. The holiday season is nearing its end; in a few weeks "summer time" will be no more, and we shall find that although on one afternoon we may be able to work up to four o'clock, on the next we shall be no better off at three, and all by Act of Parliament. Trade is still dislocated, manufacturing is sluggish, and the question of imports seems as far from settlement as ever. To come from the general to the particular, this means that photographers will shortly need their electric-light installations, and that the supplies of lamps and material are still far from normal. It is, therefore, desirable that installations should be overhauled so that any fittings or material needed should be ordered at once: that the almost inevitable delay causes the least possible inconvenience. Among the jobs which may be advantageously put in hand are the cleaning and adjustment of arc lamps and the ordering of any necessary spares in the shape of glasses and carbons, the re-whitening of reflectors, the cleaning or renewal of diffusers, and the examination and cleaning of switches, contacts, and the like. Even half-watt installations will not run for ever without a little attention. The bulbs lose much of their actinic power before the filaments actually break, and it is false economy to delay renewal till this happens. It must not be forgotten that not only the inside but the outside of electric bulbs becomes coated with dirt which becomes baked on and defies ordinary wiping. This may be removed by rubbing with methylated spirit to which a little ammonia has been added.

* * *

Reducing P.O.P. Prints. Perhaps we may permit ourselves to supplement a remark of our contributor, "Practicus," recently to the effect that he was unable to recommend any preparation or formula for reducing the depth of gold-toned P.O.P. prints which had been printed too dark. In our experience the persulphate reducer is one which works excellently for this purpose. If our contributor's view is that no reducer can be used on an over-printed toned P.O.P. print without affecting its colour, then we are bound to agree with him, but at the same time the persulphate reducer, while readily effecting the required reduction in depth, alters the colour of the print rather favourably than otherwise. It is some years now since we used it, but we still clearly recollect the excellent tone, something in the direction of a cold black, which is produced by it. Another reducer which has a very similar action, and in our experience is quite satisfactory in use, is that worked out by Mr. Hadson, and consisting of about 10 grs. of potassium ferricyanide and 20 grs. of ammonium sulphocyanide dissolved in 4 or 5 ozs. of water. It cannot be denied that these reducers are inadequate when the object is to reduce, say, one of a dozen prints in order that the whole lot may be identical, but they have their use in cases where a single print is being made and where a mistake in printing, unless it can be rectified, may lead to some considerable loss of time in taking a second impression from the negative.

Fallacies. The lack of knowledge of its first principles is, as many of us have reason to know, a distinguishing feature of many people who have to do with photography. For our sins we were condemned the other day to the long and ungrateful task of trying to prove to the enthusiastic inventor of a camera accessory that the mere device of attaching a finder to the lens did nothing towards showing the alteration of the picture on the plate when the lens was raised or lowered in relation to the latter. Failing the opportunity of ocular demonstration, the attempt was fruitless, but perhaps specific mention of the fact "in print" somewhere may bring conviction of the error to our enthusiastic visitor. Within a few hours of this incident we heard of a photographer of some experience gravely recommending the stopping-down of the lens employed in enlarging for the purpose of securing sharp enlargements of negatives which are out of focus. Cases such as this force one to the uncomfortable conclusion that many people get a knowledge of photography in a parrot kind of way by assimilating isolated items of information without acquiring any real understanding knowledge of the elementary principles which are concerned in the formation of an image by a lens. In the absence of the desire or aptitude to come to such an understanding, apparently the most excellent of text-books are useless to them.

NOTES ON ORDERING HALF-TONE AND LINE BLOCKS.

PHOTOGRAPHERS who have occasion to purchase photo-engraved blocks for their own use or often for that of their customers are perhaps, many of them, none too fully informed as to many of the points concerned in the supply of these articles as a condition of securing the best technical results, and of avoiding unnecessary charges. Like a host of other commodities the price of half-tone and line blocks has very greatly advanced during the last five years. Whereas half-tone work could be bought before the war at the price of 5d. per inch, and from some engravers for considerably less, the minimum charge for copper half-tones adopted by the Federation of Master Process Engravers is now 10½d. per inch, to which must be added correspondingly increased charges for such extras as are commonly required in buying blocks. While photo-engraving in pre-war days was the subject of a good deal of "cutting," it may be thought that process houses by combining together have very fully covered themselves in respect to the increases in materials and labour, the latter the chief cost in the making of blocks. Therefore, some notes on the ordering and purchasing of engraving work may perhaps be of value to many readers in the way of saving expense on some items, and in avoiding disputes arising from the necessity of re-making plates which are judged unsatisfactory.

The question which immediately arises is the kind of print which will yield the best half-tone block. Opinion is still somewhat divided, but it may be said that for fine half-tone work which is to be printed on an art-surface paper a well-toned P.O.P. print is probably the best form of original. Nevertheless, a bromide or gaslight print of semi-glossy surface, a surface such as that of the Wellington "Carbon" bromide, runs it very close. Even so, there is no need to dismiss a print of fine matt surface as unsuitable for a half-tone original; we have had some of the finest blocks which have passed through our hands from dead matt platinotypes and platino-matt bromides. Despite the fact that the glazed bromide is largely in favour for half-tones to be used in newspaper printing,

we are of the opinion that any of the foregoing descriptions of print are better than stripped bromides for the finer grade of half-tone required for printing on art paper. Where the subject lends itself to it, for example, in the case of photographs of buildings, it should not be forgotten that a greatly improved half-tone results from a little judicious strengthening of the contrast of the print by working up in crayon powder or by other means. The half-tone process has a somewhat flattening effect upon contrast, due to the fact that the highest light in a half-tone impression must be a tint due to the most open dot pattern formed on the plate. This effect can be compensated for fairly well by a corresponding strengthening of the darker tones in the original. It does not require much experience to be able to judge of the degree of flattening which the reproduction in half-tone causes, and to allow for it in advance. It is much better to do this than to give a somewhat vague instruction to the engraver to "brighten up the original a little."

The print should be somewhat larger than the half-tone block is to be. While it is quite practicable to make a half-tone the same size as the original or even to enlarge to some extent in making it, photo-engravers are accustomed to work upon a moderate scale of reduction in making their half-tone negatives. This degree of reduction may be put as about two-thirds scale, that is to say the original for a block which is to measure 4 inches should be about 6 inches. To avoid confusion, the back of the print should be plainly marked with the dimension which the half-tone is to have. Mistakes are often caused by instructions to make a block "half-size" or to reduce "two-thirds," because there is the opportunity to mix up size and scale. For example, a 4 by 3 block from an 8 by 6 original is quarter-size but only half-scale. By giving always actual dimensions this source of error is eliminated. Also, where several quite small blocks are required, economy may be effected by ordering them to be reduced together in making the half-tone negative and the engraved plate from it, the plate being then cut up and the portions separately mounted. At the present time photo-engravers charge 12s. 3d. for what they call the "minimum" size of block, namely, one of 14 square inches. Any single block smaller than this is charged the full 12s. 3d., so that if several little blocks measuring, say, 2 by 3 inches have to be made, it is economy to prepare them of such size that they can be reduced together to give blocks of the required dimensions. There is a limit to this economy, since engravers now agree to charge sixpence for the cutting out and separate mounting of each plate which they prepare in the first instance from several originals in this way. Moreover, the best results cannot be expected unless the originals are of similar tone or colour; it is useless to order the reduction of a black and a sepia print together, one or the other is bound to suffer. In ordering blocks to be reduced together in this way the proper plan is to mark a dimension on one only, which may be called A, and to pencil on the others "reduce with A and cut," or "with A, as it comes." The accompanying order should be written in a corresponding manner, for example:—

1 half-tone marked A	}	←	3 ins.	→
1 " " B		Reduce together and cut.		
1 " " C				
1 " " D				

In exceptional cases it may be necessary to order a block of size just to fit in a given space. Here it must not be forgotten that the bevelled mount of the block, or the "beard," as printers call it, averages about one-eighth of

an inch all round, so that the whole block as a rule is a little more than one-quarter inch larger each way than the picture on it.

A further point in ordering blocks is the ruling of the screen used in making them. For general work on art paper or for good qualities of esparto and other calendered papers the best screen ruling ranges from 133 to 150 lines per inch. Almost without exception it will be found that 133 lines per inch is quite sufficiently fine. Blocks made with finer screens are more difficult to print, and therefore in the end may give a worse result than those from screens of coarser ruling. For the poorer classes of paper, such as used for newspapers, screens of greater coarseness from, say, 100 to 85 lines per inch are used, but these will be rarely wanted by the photographer except for the purposes of advertising in local newspapers, in regard to which it requires to be said that the reproduction in the best circumstances is never likely to do anything like justice to the original photograph.

Half-tone blocks are finished off by photo-engravers in various ways. It is the common practice to put a rule or line round the picture. Most engravers do this without it being ordered, but we think any half-tone engraving which is supposed to have any claim to pictorial merit looks much better without it. If it is not required, the fact should be separately indicated on the order by the words "no rule." Another variety of finish is that of cutting away the background of a subject on the block so that the subject appears, when printed, against the white paper instead of against the half-tone tint or any design of background which might have been in the original. This "routing," as it is termed, is charged at a somewhat higher rate per inch, as is also the vignetting of a subject on the block. A further form of extra work which the engraver does (and charges for) is "piercing," that is perforating both the wood and the metal of a multiple block for the purpose of providing space for the insertion of type.

Before we leave the considerations of half-tones there is one point which requires to be explained to those who set any store by the correct tonal reproduction of their originals. It applies particularly to work in a high key and to any prints the tones and gradations in which are delicate. This is the question of "fine etching," which is the retouching work which the artists' department of a photo-engraving shop carries out by covering parts of the engraved plate with an etch-proof varnish and then giving the portions which are left uncovered a further etching. In our opinion, formed from a twenty years' experience in ordering half-tone engravings, this fine etching is the bane of the half-tone process when a facsimile reproduction of tones is concerned. We know too well what the fine etcher can do towards "improving" the block. His improvements are very often done to remedy defects in the photographic part of the process, that is to say, in the making of the screen negative from which the engraved plate is printed, and we have seen for ourselves the extent to which the fine etcher will falsify the tones in a reproduction and even outlines themselves, as, for example, cloud forms in a sky. But the practice is so firmly established in the photo-engraving trade that there is no prospect of getting rid of it, although it has been shown that the half-tone block is able to give an almost facsimile reproduction without any fine etching whatever. We make these remarks for the benefit of photographers having the occasion to order half-tones which shall reproduce as correctly as possible the tonal values of the original. In these circumstances it is advisable to instruct the engraver to omit fine etching altogether. When, as is almost certain to be the case, he says that he cannot, the reply should be that fine etching is to be done to the very minimum extent. Photo-engraving establishments vary in their ability to give

facsimile results, but a little experience of block-makers will enable the purchaser to place his custom with one which depends more largely on the photographic work than upon the touching-up of the fine etcher. As regards half-tones, a final word requires to be said, by way of caution, that the effect shown by the proof supplied by the engraver cannot be expected to be repeated in as high a quality when the job is printed. Allowance must be made for the superiority of the etcher's proof over the impression which the printer of a booklet or circular is likely to give.

Line blocks are less frequently needed by photographers, and may be briefly dismissed by saying that proper quality of the original—that is, solid black lines on white board—

is more important than is that of the original for half-tones. On the other hand, makers of good line blocks are more difficult to find than those of half-tones. As regards the economy in making several small line blocks together, the observations already made under half-tone apply equally. Apart from such line blocks as a photographer may use for newspaper advertising, his chief demand for them is likely to be in the way of composite blocks containing both line and half-tone, for example, the half-tone reproductions of some photographs interspersed or surrounded with decorative work in line. This is a regular product of the photo-engraver, and some most effective work of this kind can be obtained.

NIGHT PHOTOGRAPHY.

[Perhaps no branch of outdoor photography offers so great a degree of attractiveness as that of outdoor scenes under artificial illumination, particularly to those in large cities where an abundance of subjects of this kind is available. Since the immediately forthcoming season is the best time of year for night photography we take the opportunity of publishing a comprehensive practical article on the subject by an expert in it of long experience, Mr. Robert Dykes, F.R.P.S., formerly senior scientific assistant to the late Sir John Murray, K.C.B., F.R.S., and of the North Sea Fishery Investigations. Part of these notes appeared in a manual on night photography by Mr. Dykes, issued some years ago by Messrs. Dawbarn and Ward, but long out of print. In this final instalment Mr. Dykes describes a method of introducing night and interior subjects into cinematograph films.—Ed. "B.J."]

(Continued from page 518.)

Methods of Obtaining Cinematograph Night Effects.

For the benefit of those readers who have not used, or do not understand the mechanics of, cinematography a brief outline of the movements may be an advantage. The cinematograph is simply a glorified form of snap-shot camera, which takes single pictures on a continuous ribbon of film, each little picture being perfect in itself and measuring about one inch wide by three-quarters of an inch high, so that at all times and for all subjects the height must be accommodated within the three-quarters of an inch, there being no vertical or horizontal positions for picture-taking as in the ordinary camera. Neither is there a swing-back, hence the frequent distortions in cinematograph pictures through too much use of the tilting-table and bad camera setting.

Continuous movement of the film past the lens, without a pause would give a blurred image, similar to the effect obtained when, in taking ordinary photographs, the camera is moved during exposure. To overcome this difficulty in the cinematograph camera the film or negative stock is fed intermittently behind the lens, through a pressure gate, by special gear, which feeds with a quick, jerky motion. The recognised rate of speed to obtain almost natural movements of the objects photographed when projected upon the screen has been found to be one foot of film to the second, there being sixteen pictures in each foot of film. The camera handle is given two complete turns per second, so that it will be understood that each single picture is taken at an exposure of about 1-45th of a second, there being a corresponding period of time for the shutter to cut off the light, whilst the intermittent gear brings a fresh portion of cinematograph film into position ready for exposure. The sector of the shutter may be opened or closed, to increase or decrease the exposure, but the general exposure is 1-45th of a second.

The intermittent motion of the film is obtained by means of a claw escapement worked by an eccentric movement, the two claws engaging in the sprocket-holes or perforations on each side of the film stock, and as the closed portion of the circular shutter working between the lens and the film cuts off the light these claws draw the film downwards three-quarters of an inch, disengage, and as the open sector of the shutter travels across

the film giving the exposure, the two claws travel upwards three-quarters of an inch, then forwards, and, as the open sector of the shutter passes out, they engage the sprocket-holes of the film and bring down another three-quarters of an inch of unexposed film. By this means a steady, intermittent movement is kept up, the film running from a magazine holding rolls of from 50 feet to 400 feet, according to type of camera. As the film leaves the magazine it passes under a jockey roller, then between rollers and a sprocket-wheel into the gate over *skates* or *runners*, kept gently but firmly in position by springs. On leaving the gate, the film again passes under a sprocket-wheel over rollers, under a jockey roller, and into the take-up box, which is exactly similar to the magazine and interchangeable. The gate carries the "mask," a small, highly burnished plate of gun-metal or steel having a square cut opening about one inch wide by three-quarters of an inch high. These masks vary slightly in different cameras, and it is essential that films made up for projection should always have the same masking.

With these few particulars about cinematograph camera movements my readers will readily understand that certain subjects are next to impossible in cinematography. Some cine-cameras are specially geared for trick work, etc. A separate low gear enables the operator to take single pictures per one turn of the handle at any desired exposure.

It may be mentioned briefly that variations in speed of taking are introduced at times for certain purposes. The regular speed of handle turning to give fairly correct animation has been found to be about two turns of the handle per second, which gives the sixteen pictures to the foot. If the handle is slowed up, moving objects photographed, such as a man walking at a moderate pace, will appear to move much faster and will do so in more or less spasmodic jumps, the number of single pictures taken not having been sufficient to deceive the eye and give the apparent natural gait. If, on the other hand, the handle is run too quickly too many pictures may be taken to show the natural gait, and the result is a heaviness of movement or exaggerated slowness very frequently seen in topical pictures of soldiers on the march, the operator having raced or kept time to the band. Motor-cars scooting up roads and hopping round corners is done by slow handle-turning, and high jumps and other rapid movements showing slowness are

done by high-speed handle-turning on specially geared machines taking forty pictures and over to the second, and projection on the screen at the ordinary speed.

When a cinematograph film is projected upon the screen there are as many gaps or periods of blank as there are pictures, but unless we introduce a special means of detecting them the eye is deceived by what has been termed the persistence of vision, an optical illusion easily illustrated by watching someone rapidly whirl a red-hot poker or a lighted torch round his head, when an apparently continuous circle of light is observed, though it is obvious that the poker or torch can only be in one spot at a time. Persistence of vision, or optical continuity, fills up the gap.

It is this deception the optic nerve plays upon the brain that gives us the impression of continuous movement in the figures or objects projected upon the cinematograph screen. The effect is killed by broadening the gap between each picture by means of a white line space between each separate picture. The film on projection then becomes a series of "stills," or ordinary lantern-slide type of picture that fail to coalesce, no matter at what speed they may be projected, and are therefore without animation. The brain is more susceptible to white than black, and the white space between the pictures completely destroys the illusion. It is possible therefore to realise the fact that there is a gap between each single cinematograph picture of about the same length of time as that occupied by the picture on the screen. Therefore, when we go to see the pictures at a cine. show we see nothing half the time, but we do not know it—shure, but 'tis a dirty trick that our senses play us.

For picture purposes the shortest length of film that one can use without it simply being a flash, is eight or ten feet, equivalent to 10 x 16, or 160 single pictures. With a shorter length of film than this the picture would be on and off the screen without allowing sufficient time for viewing. This makes it a matter of impossibility to include such scenes as cathedral interiors and night effects without taking them by studio methods of lighting, i.e., the introduction of arc lamps or mercury-vapour tubes. By the ordinary lighting in a cathedral or a street scene by night, even were we to use the trick handle of the cinematograph camera and expose one picture per turn at the required exposure, it would take, as a general rule, a considerable length of time, with consequent fluctuations of light and other difficulties. Consider cinematographing Edward the Confessor's Tomb in Westminster Abbey without panoraming. It would be a direct still life length of film of twelve feet (12 x 16) or 192 single pictures at an exposure of forty minutes per picture on the film stock (200 H. and D.: lens aperture $f/3.5$), or one hundred and twenty-eight hours' handle turning. Scenic, or travel pictures, therefore, have been limited to pure outdoor subjects, and in making a travel film of a cathedral town an operator had to confine his attentions simply to exterior views of the cathedral or other interesting buildings.

It is impossible in a picture theatre for the operator to stop running his film for the purpose of projecting ordinary lantern slides on the screen showing interiors. Therefore, to make scenic and travel films more interesting and complete, the following method was tried by the writer with great success, and will enable an operator to introduce lengths of cinematograph film negative of both night effects and cathedral interiors into his ordinary film negative taken direct with the cinematograph camera. In the first place, this method is simply a copying process, and ordinary plate negatives must be taken first. Films are of no use, as they will not enlarge satisfactorily without showing the grain of the celluloid base. The type of negative selected for conversion into movies must not contain moving objects, such as life, smoke, or clouds, unless the subject is of the greatest importance and unobtainable by direct cinematographic means. The only animation we can introduce into these travel stills is a panoramic movement, moving generally from

left to right or up and down as in some cathedral views. If any form of life were in the negative to be copied it would require to be on the extreme edge, where one would immediately panoram off it, otherwise the figure or figures would look like models in a waxwork show. The best size of plate to use is from half-plate upwards or, if using quarter-plates, to enlarge up to half-plate or larger. A transparency is made either by contact or enlarging, and this is copied by the cinematograph camera on to cinematograph film-negative stock. A half-plate transparency if panorammed across from left to right of the length of the plate will yield according to distance of transparency from cinematograph lens a length of film negative of from eight to fifteen feet.

The transparency is mounted in a carrier, which may be geared to move absolutely steadily across the front of the cinematograph lens from right to left by means of a ratchet turned by a handle and so threaded that the plate may be moved sufficiently slowly to allow of the required length of film negative being taken. This carrier may be very simple in construction or elaborated into a series of horizontal and vertical movements controlled by the cinematograph camera itself by suitable gearing. One thing absolutely essential is perfect steadiness of movement. To simplify matters the cinematograph camera may be panorammed across the transparency by means of the ordinary panoram gear attached to all cinematograph tripods.

The ciné pictures of Stockholm, Sweden, from the Katarina Hissin, and others, reproduced August 22, were copied in this way, and are perfectly steady when projected on the screen. They were copied by means of the slow handle at about four pictures to the second with a three-inch lens five inches from plate and stopped down to $f/11$. The lens tube of a ciné camera is as a general rule of sufficient length to allow of focussing up

closely, but if not it is a simple matter to increase the length by introducing a short piece of tube. In panoraming with the ciné camera the lens moves through a small angle, but as the lens is of such short focus this angle is inappreciable.

The transparency for copying is lighted by any suitable means such as daylight, incandescent gas, acetylene, or a small arc through a condenser sufficiently large to cover the size of transparency to be copied and a ground-glass screen to equalise the light (see diagram). By this method, providing the handle-turning is steady, the exposure right, and the light good, a length of film negative of superior quality may be obtained that, when joined up in the real ciné film, will give just that suggestion of movement that is required for cinematograph pictures.

It makes a travel film much more interesting and complete if

we can introduce interesting subject matter that may be of historical value, such as the spot where Thomas à Becket was assassinated in Canterbury Cathedral, one spot that has made the old cathedral famous and brought many thousands of pilgrims from all parts of the world to see.

A year or two before the war the writer introduced some of his experiments into a film of Winchester, showing the nave, choir stalls, screen, etc.—three short lengths of novelty—and increased the interest in the film very considerably. They were judiciously sandwiched in and did not total more than forty feet.

If we desire to introduce more animation and suggestion of life into cinematograph pictures by night as in the case of picture-play work, where it may be desirable to introduce a street scene by night it will be necessary to adopt American methods as carried out at Universal City (a cinematograph town), Los Angeles, where real street settings are arranged and lighted by quartz mercury-vapour lamps. There is another method, but a very tedious and difficult one that, as far as the writer is aware, has not been used, though some people claim to have carried it out, in all probability assisted by mercury vapour lighting and "spot lights." The idea is to expose doubly, first, on your characters in the scene against a dead black background so arranged that when the film is exposed or runs through on the street scene by

night, the characters in the setting occupy a dark part of the picture, where no lights can shine through them. The writer carried out a series of experiments some few years ago with the ciné camera at night in the West End of London, and the results were both interesting and very funny. The exposures made were with the usual film stock (200 H. and D.), and a lens working at full aperture ($f/3.5$) on the high gear or ordinary handle turning 1-30th to 1-40th of a second, and on the low gear or trick handle at from four pictures a second or $\frac{1}{4}$ second exposures to five seconds a picture. The best results were obtained by the longest exposures, but in such scenes as Piccadilly Circus the results were too funny to be used seriously owing to the movement. The traffic trafficked and the policeman on point duty did a week's work in a couple of minutes. 'Buses were pushing each other up Shaftesbury Avenue, and signs were "verra thick." The effect was much as a West-End may have seen it in pre-war days after having dined too well but not too wisely. As before explained, this effect was due to not obtaining the required number of pictures per second to give the apparent natural movement.

I will close these notes on the cinematograph in the hope that it may be found of use to amateur cinematographers, and that it may lead to bettering the output of educational and travel films—a somewhat neglected branch of the industry, but of great promise in the near future.

ROBERT DYKES, F.R.P.S.

PRACTICUS IN THE STUDIO.

[Previous articles of this series, in which the aim of the writer is to communicate items of a long experience in studio portraiture, have appeared weekly since the beginning of the present year. It is not thought possible to continue the series to the length of that by the same writer which ran through the "British Journal" some years ago, but if any reader among the younger generation of photographers, and particularly those engaged as assistants, has a particular subject which might be dealt with, his or her suggestion will be welcomed. The subjects of the previous articles of the series have been as follows:—

A Talk About Lighting (Jan. 3).
The Camera and the Lens (Jan. 10).
Managing the Sitter (Jan. 17).
Backgrounds (Jan. 24).
Studio Exposures (Jan. 31).
Artificial Lighting (Feb. 7).
Printing Processes for Portraiture (Feb. 14).
Studio Accessories and Furniture (Feb. 21).
The Surroundings of the Studio (Feb. 28).
Studio Heating and Ventilation (March 7).
The Postcard Studio (March 14).
The Printing-Room (March 21).
About the Reception Room (March 28).
Home Portraiture (April 4).
Portable Studios (April 11).
Copying (April 18).
Handling the Studio Camera (April 25).
More About Lenses (May 2).

Enlargements (May 9).
Advertising the Studio (May 16).
Mounts and Mounting (May 23).
Business Methods (May 30).
Photographing Children (June 6).
Portraits of Elderly People (June 13).
Something about Lenses (June 20).
Hand Cameras for Professionals (June 27).
The Dark-Room and Its Fittings (July 4).
Plates and Their Work (July 11).

The Keeping of Negatives (Aug. 22).
Reduction of Negatives and Prints (Aug. 29).
Leaky Roofs (Sept. 5).

BLINDS AND CURTAINS.

ALTHOUGH in previous articles I have touched upon the use of blinds and curtains for studio portraiture, I have not discussed the pros and cons of the various methods of light-control in general use.

Putting aside for the moment portable shading appliances, we may consider that there are two systems to be considered—roller blinds of the usual type and festoon curtains. Each of these systems has its supporters, and practically the same effects of lighting can be obtained with either. The main points of difference are found in the cost of installation and repairs, the ease of working, and, in a lesser degree, the appearance when fixed.

Most writers upon studio construction and fitting seem to favour roller blinds, perhaps because they have been more familiar with them than with curtains. I confess I do not share this view, but I am quite willing to state the case for blinds as

fairly as possible. It is usual to have two complete sets of blinds: one set of dark green or very dark blue and the other of pure white. The material in each case is good quality "blind holland." There may be a temptation to use tracing cloth for the white set, but this should be sternly repelled, as tracing cloth becomes very brittle with exposure to the light, and tears and splits in all directions. Good holland does not behave in this way, and, moreover, can be washed and re-stiffened when soiled. The edges must be hemmed to give additional strength, as the pull of the springs is necessarily strong. Below each roof blind two strong guide wires must be fixed to prevent sagging. Overlap of five or six inches must be allowed, so that oblique streaks of light may not fall upon the sitter.

We have now to consider the width of each blind. For a studio 28 feet in length, and entirely covered with glass, H. P. Robinson recommends six blinds, each 4 feet 8 inches wide; but

this seems to me to be too wide, as the raising or lowering of even one blind of this width may alter the lighting to a greater extent than is desired. On the other hand, narrower blinds mean a greater number of rollers and a complexity of wires and strings for managing them. Modern studios, however, have usually less glass to cover, and I should prefer blinds 42 inches wide, five of which would be sufficient for a run of about 15 feet, allowing for overlap. The rollers must be of stout tin with good springs and ratchets, as the cheap wooden rollers are not strong enough for this work, and the ratchets are not reliable. The cords must run over brass pulleys fixed at the eaves and be secured by cleats at a convenient height from the ground. Naturally the dark blinds will be fitted with dark cords and the white blinds with light ones, or endless confusion will result. The side blinds must correspond in width and number with those of the roof, and their rollers must be fixed at the bottom of the windows, the cords passing over pulleys at the eaves and secured to another set of cleats. This gives twenty strings to look after in a range of five blind widths.

As long as the blinds continue in good working order there is no fault to be found with this arrangement; but as soon as the springs begin to weaken or the blinds acquire a habit of running unevenly the trouble begins, and there is considerable difficulty in putting matters right. This is usually due to the common practice of leaving the blinds down when not in use. If all the strings are released and the blinds allowed to roll up during the night, the springs will retain their resiliency and the blinds will run more truly, besides which the rotting effect of the light upon the material will be reduced to the minimum.

The festoon curtain system is equally efficacious in use and much simpler and cheaper in construction. It calls only for four wires stretched tightly from end to end of the studio, upon which the curtains run, both dark and light blinds running upon the same wires. The top wire should be fixed as near the ridge as possible and a little beyond the centre beam, so that no light can creep over the top of the blinds. If this be not possible about six inches of the glass should be obscured with dark paint which will serve the same purpose. The length of the curtains will depend upon the length of the glass to be covered. In most studios two rows of curtains will be sufficient, so that each will be half the length of the glass, allowing also for an overlap of six inches. The third wire, which supports the top of the second row of curtains, should not be in the same plane with the other three, but about five inches lower, so as to allow of the two rows being moved to and fro without fouling each other. The wires should be of galvanised iron, which will not corrode like plain iron or steel, nor perish like brass. Copper is too soft, and will give under the strain. The curtain rings should be about three-quarters of an inch in diameter, so that they will slip over the straining bolts without having to untwist the wire. They should be sewn about 5 inches apart on to a strong linen tape which is firmly stitched to the hem of the curtain. Enough black or dark

curtains should be provided to cover the glass entirely, and in the centre there should be enough white curtains to cover half the length of the glass.

The side blinds hardly need description, as they are fitted in two rows exactly as for an ordinary window. The arrangement and proportion of black and white is the same as for the roof. Sketches showing the general arrangement will be found in the "Portrait Studio." The best tool for manipulating the blinds is a bamboo cane fitted with a large cork ball at the top. This will give a good hold on the material without risk of tearing.

The size of the studio has an important bearing upon the effect of the blinds, a little modification of the latter altering the lighting to a much greater extent in a small studio than in a large one. In fact, in a very large and lofty studio it is often necessary to provide a portable arrangement of curtains which can be brought close up to the sitter when any decided effect of lighting is desired. I recall one studio of such immense proportions that the only possible means of controlling the light was to block out everything but one side window, which was used as a high side light in the manner of Robinson's "studio of the future." The studio in question is now one of the past as far as photography is concerned. The idea of using a portable curtain carrier originated, I believe, with the late Robert Slingsby, who had to contend with a high-roofed studio. A convenient arrangement is a frame about six feet wide and seven feet high fixed upon feet similar to those of a background. On the top of this frame is fixed another about three feet wide at an angle of about 35 degrees from the horizontal. On the upright frame are two rows of curtains of nainsook or nun's veiling running on wires, while the top frame has one row, similarly fixed. If desired, the top frame may be hinged and fitted with a clamping arrangement so that the angle can be varied. With this simple appliance some charming and distinctive effects of lighting can be obtained with very much less trouble than with the ordinary fixed blinds; in fact, I have worked the day through without having to touch the large studio blinds at all. In the case of electric-light work where the ordinary blinds cannot be used, this screen is invaluable and allows of much better control than is possible with any other system I have tried. If it be found necessary, it is, of course, possible to add dark blinds by hooking them on to the wires.

In very small studios where there would be no room for this screen, the sitter is nearer the light, and control is easily obtained by the blinds. I recommend in addition an ordinary circular head screen, which should be covered with thin muslin. The lawn usually fitted is rather too thin, while calico or tracing cloth is too thick. If a second head screen can be provided it should be covered with a thin black gauze, which reduces the light without diffusing it. This will be found very useful for reducing the light on white drapery or for casting a slight shadow on the lower part of a figure.

PRACTICUS.

A PLEA FOR THE OZOBROME PROCESS.

[The form of carbon printing represented by the Ozobrome process is unfortunately one of those methods which, though simple and expeditious in practice, assumes a forbidding complexity when described in print. A contributor, Mr. W. H. Moffitt, to the "Australasian Photo Review," has made a courageous attempt, not perhaps entirely successfully, to present the working instructions of the process in a form corresponding with the facility with which they can be carried out. Inasmuch as Ozobrome is pre-eminently a variety of carbon printing which scores particularly over its prototype during the winter months, Mr. Moffitt's notes may perhaps be read with interest by those to whom the process has hitherto been an unexplored field.—EDS. "B. J."]

It is remarkable that a process so fascinating and full of artistic possibilities as the Ozobrome Process should need any advocate; yet, so far as I am aware, there are very few people here (Australia) working at it. I hope this article will induce more to adopt the process.

Now I quite admit that Ozobrome can scarcely be called a be-

ginner's medium: (1) In the first place, it calls for a good bromide (or gaslight) print, and it is astonishing what a number of photographers there are who find difficulty in producing a really good bromide print, and the still greater number who slur over the finishing stages, viz., fixing and washing. By a good bromide print I mean one of a good pictorial subject, and properly

exposed, developed, fixed, hardened,* and washed. (2) In the next place, it calls for exactness, care, and thoroughness in manipulation, qualities not conspicuous in most beginners' work. (3) Lastly, it is hardly worth the time involved to make an Ozobrome of a print containing as little evidence of artistic perception and selection as the prints of the average beginner.

But Ozobrome is not difficult (I emphasise this), and anyone who wants to make a picture in a medium offering all the advantages of carbon—permanence, variety of colour and surface, superior gradation, richness of shadow, and control (the last-mentioned to a greater degree than carbon)—and the following important additional advantages:—

(a) Independence of light, and the consequent abolition of daylight printing, actinometer, and printing frame.

(b) Suitability of any negative that will give a good print on bromide or gaslight paper, *i.e.*, practically any printable negative.

(c) Enlarged pigment prints without enlarged negatives;

Anyone who can make a good bromide or gaslight print as above defined will find in Ozobrome not only a process that yields most beautiful results, considerably superior in many instances to the bromide prints from which they are made, but also one that from beginning to end is most fascinating in all its details. (I have often spent from 7 p.m. till midnight making Ozobromes, and scarcely noticed the flight of time.) Only simple apparatus is required; Ozobrome is not expensive.

The following are formulæ found satisfactory for the pigmenting (bleaching) and acid baths:—

A. Pigmenting and Bleaching Solution:

Potassium ferricyanide	30 grs.
Sodium (or potassium) bichromate	10 grs.
Potassium bromide	10 grs.
Water	5 ozs.

B. Acid Bath:

Citric acid	15 grs.
Oxalic acid	22 grs.
Chrome alum	20 grs.
Water	30 ozs.

Both formulæ can be made up to three or four times the working strength, and in larger quantities for stock solutions. Even at working strength they keep indefinitely, and the used solutions for at least a week.

The following description of the *modus operandi* will, it is hoped, give a clear idea of the process, but the reader will bear in mind that description is necessarily more cumbersome than demonstration, and will not take fright at what, admittedly *seems* somewhat complex.

There are two methods of procedure, the transfer and non-transfer; I will describe the non-transfer first.

Arrange four dishes in a row on a table—

Fill (1) and (2) with water, (3) with sufficient acid bath, (4) with sufficient pigmenting and bleaching solution. Dish (2) should be much larger than the print to be made.

Have a watch recording seconds handy. Put the dry bromide in dish (1), the carbon tissue (which for the non-transfer method should be a little *smaller* than the bromide print to prevent frilling) in dish (4). Leave the tissue till it is quite limp, then lift it by the corner and drain for about 15 to 20 seconds, *according to the result desired*. (See below.) Drain for 10 to 15 seconds, and

* Hardening is necessary for the non-transfer method, and advisable for the transfer method. The best acid fixing and hardening bath I have used for all purposes is from a formula I found in the original Ozobrome book of instructions. It is as follows:—

A—Hypo	1 lb.	Water	40 ozs.
B—Potassium metabisulphite ..	1 oz.	Water	20 ozs.
C—Chrome alum	1 oz.	Water	20 ozs.

For use, 2 parts A, 1 part B, 1 part C.

pass into dish (2), face downwards; draw the tissue gently across the surface for about double its own length, still face downwards; lift it out and slide it again under the water *face upwards*. (Be very careful if you want uniform results to do this drawing and sliding process in the same way every time, as this regulates the quantity of solution and acid bath left in the tissue to work on the bromide print and set up the chemical action which renders the tissue more or less insoluble in proportion to the gradation of the bromide print. If too much is washed off, the bromide will not bleach thoroughly and detail will be lost, whilst the resulting pigment print will be harsh and greatly intensified, but with loss of detail in the shadows. If a surplus is left in the tissue the resulting print will be lacking in depth and the high lights will be veiled. Any intentional modification of contrast should be done by a longer or shorter immersion in the acid bath—20 seconds for normal, 10 for contrast, 30 for flatness. Very broad effects can be obtained by printing the bromide rather lightly and giving the plaster 5 to 10 seconds' immersion.)

At once lift the bromide print from dish (1) and slide it face downwards under the water in dish (2), bring into contact with the tissue, which is face up, *under the water*. Lift them out clinging together, lay on a sheet of glass, and squeegee lightly but firmly into contact. *Leave for 20 minutes to an hour*. (During this interval several other bromides can become acquainted with treated tissues in a similar manner.)

Now get a basin of hot water, as hot as can comfortably be borne. Have a kettle boiling to keep up the temperature for the succeeding prints. Put the plaster and adhering bromide print into the hot water, wait a few seconds until the soluble tissue begins to ooze out at the edges, then strip off with a gentle unbroken pull the tissue backing and throw it away. Gently dash the hot water over the bromide print, which now supports the *insoluble* pigmented image (the bromide image being bleached out as in the ordinary operation preliminary to sulphide toning). The soluble pigmented gelatine soon washes away leaving the insoluble gelatine image super-imposed upon a bleached silver print. Rinse in cold water for a second or two, and hang up to dry. When dry, fix out the bleached silver image with ordinary strength hypo, wash and dry.

If desired the bleached image may be redeveloped wholly or in part with any ordinary developer, or may be sulphide toned, considerable control being possible in this way. Control is also possible while the hot water development is in progress, as in the case of ordinary carbon work, by applying hotter water locally, or by rubbing parts with the ball of the forefinger. The gelatine image is very tough as a rule, unless a longer than normal immersion in the acid bath has been given, or a surplus of acid bath remains owing to insufficient rinsing before bringing the tissue into contact with the bromide print, in either of which cases it is more readily injured. Normally it is much tougher than in the case of the ordinary carbon method, and in the shadows will stand quite a violent rubbing without injury; a little experience will soon show how much. The half-tones and high lights are more delicate owing to the thinness of the gelatine.)

The Transfer Method.

This is greatly to be preferred (unless it is desired to avail one's self of the method of control referred to above by redevelopment of the bleached image), and for these reasons:—

The resulting picture is composed of pigmental gelatine only;

Any surface may be used to support it;

The original bromide is available for further use;

It is no mere troublesome, as although another squeegeeing is involved, there is no fixing and washing required. (Either method gives a non-reversed picture.)

The procedure is precisely the same as in the non-transfer method down to squeegeeing the bromide and treated tissue, but at the end of the specified time (20 minutes or upwards), put the adhering bromide and tissue into *cold* water, and separate them. This is perfectly simple, and you then hold in one hand the bleached bromide and in the other the plaster, which *looks* just the same as before contact with the bromide, but is in reality insoluble wherever the chemical action has taken place. Drop the bromide into another dish of water, and forget about it *pro tem*.

Take the plaster; as the whole substratum of gelatine is unacted upon and therefore soluble, it is clear that if the plaster were placed in hot water the substratum would dissolve and the insoluble image crumple up and float away. (It would in any case be reversed.) We must therefore get the soluble substratum uppermost before developing, and to do this we use a *transfer paper*.

This is simply good quality paper coated with insoluble gelatine. Autotype single transfer papers are ideal, and are made in all useful surfaces, but are unobtainable locally at present, largely, I am afraid, owing to the shocking neglect of carbon printing by Australian amateurs. Until it becomes available a perfect substitute can be made by fixing out and *hardening*, and washing ordinary bromide paper, using the fixing and hardening bath recommended above. Austral Pearl bromide papers are made in many fine surfaces, all quite suitable. Treat a few pieces in this way after making your next batch of bromide prints, and put them aside for subsequent use as transfer papers. (The transfer paper should be slightly larger than the tissue to prevent frilling.) Take the plaster then and bring into contact under the cold water with a piece of transfer paper, as soon as the transfer paper has become limp. Lift out and squeegee firmly into contact, using moderate pressure. (I much prefer a roller squeegee for this business, but am quite aware that in this preference I am unorthodox. Quite a small squeegee will do for the largest work, about 5 ins.) Place the adhering papers between blotting sheets under a moderate weight for 10 minutes to an hour. (During this interval you can separate several other bromides and plasters, and squeegee the plasters to the transfer papers, placing them under the same weight one on top of the other, separated only by blotting sheets.)

Now place plaster (or tissue—I have used the words synonymously throughout) in hot water, and proceed as in the non-transfer method, viz., strip the plaster backing and develop, rinse and hang up to dry. *When dry the print is finished.*

You may now turn to the bleached bromides: rinse and redevelop them in amidol (preferably) or any other non-staining developer, wash for a few minutes, dry, and they will be ready for producing a further batch of Ozobromes.

If this description of the procedure be thoroughly grasped it will be realised that there is nothing from beginning to end calling for special skill. To assist the reader to obtain a clear mental view of the process, the following outline of the different stages may be of use:—

Outline of the Non-transfer Method.

1. *Materials*.—Bromide print, piece of tissue (slightly smaller), four dishes (one very large), squeegee, pieces of blotting paper, two pieces of plate-glass (one for squeegeeing upon, the other to act as a weight), pigmenting solution and acid bath, and hot water. (The water can be heated while the print and plaster are in contact.)

2. Pour cold water into two dishes (including the large one), acid bath in another, and pigmenting solution in the fourth.

3. Immerse bromide in water; plaster in pigmenting bath till limp; drain 15 seconds, immerse in acid bath 10 to 30 seconds, drain 15 seconds; bring into contact with bromide under water (taking care to follow specified procedure), squeegee into contact (all this can be done in four or five minutes easily); leave for 20 minutes to an hour, and treat some more prints and plasters in the interval.

4. Separate in hot water, develop, rinse, and dry.

5. Fix and wash (a week after if you like).

Outline of Transfer Method.

1. *Materials* as under (1) above (but tissue slightly larger than print), and transfer paper (slightly larger than the tissue), and developer for bleached bromides (which need not be made up till all other operations are completed).

2. As under (2) above.

3. As under (3) above.

4. Separate in cold water, squeegee tissue on to transfer paper; leave 10 minutes to one hour; separate and squeegee some more papers in the interval.

5. Develop in hot water, rinse, and dry.

6. Develop bromide prints.

Some Concluding Notes.

Six to more Ozobromes by the transfer method, nine to a dozen by the non-transfer method, represent a fair evening's work—say three hours. And they will seem little longer than three minutes, so engrossing and fascinating is the process.

Frilling is almost always due to using plaster or transfer paper respectively smaller than print and plaster in the transfer method; and to using a plaster larger than the bromide in the non-transfer. Blisters are rare—they may be caused by splashing very hot water from a height during development, or by leaving the plaster for an excessive time in the acid bath.

A correspondent of the "Amateur Photographer and Photography" says: "After amusing myself with photography for the last sixty years, I have taken up carbon work, with which I have been very successful. *I wish I had tried it before.*" Reader, don't you wait sixty years—take it up now in the form of Ozobrome, and see if you don't thank me for the advice when you have acquired facility in the working of the process: three or four evenings should ensure this.

W. H. MOFFITT.

PHOTOGRAPHIC MEASUREMENT OF THE INTENSITY OF SPECTRUM LINES.

IN the course of a lecture at the Royal Institution on "Energy Distribution in Spectra," Professor J. W. Nicholson, F.R.S., described a method worked out by Dr. Merton and himself for the measurement of the intensity of spectrum lines on a comparative photographic basis by which inequalities of plate-sensitiveness in different parts of the spectrum are eliminated. While it is not possible to follow Professor Nicholson precisely in his reference to the want of relationship between the density of a photographic image and the time and intensity of light producing it, his description of the method deserves to be quoted from "Nature" of August 21 last, where the lecture is printed at length, and to which the reader must be referred for an account of the investigations and conclusions followed from data obtained in this way.

Professor Nicholson writes:—The intensities of spectrum lines have usually been recorded on an arbitrary scale, ranging between 10 and zero, the numbers assigned being at the discretion of the observer, and varying so greatly among different observers as frequently to be of little value for exact knowledge. They depend also very much on the nature of the observation, whether visual or photographic, and in the latter case on the region of the spectrum to which the line belongs. The sensitivity of a photographic plate varies with the wave-length of the light in a curious manner, and apparently an irregular one not following any simple law. The sensitivity of the eye is also different for different colours. When the line is outside the visible spectrum, in the infra-red or dark heat region, measurements of intensity can be made with some accuracy by a thermopile or a bolometer. But they are needed more urgently in the visible region at present, not only for the information they will afford regarding the nature of the atom, but also for application to other problems. The subject is very important, for instance, in the interpretation of celestial spectra, and more particularly those spectra of great complexity and variability which are associated with the birth of new stars, from which most of our knowledge regarding such stars must be constructed.

Previous knowledge of changes in spectral intensity under varying conditions was of necessity limited to the great changes. Those changes, which are of especial value in connections such as I have mentioned, are liable to be of a less conspicuous type, not readily capable of detection by the ordinary photographic or the visual method, and, if detected, not capable of accurate measurement.

In adopting any photographic method for quantitative work we must remember that not only does the sensitivity of the plate vary with the wave-length, but also that there is no very definite relation between the density of a photographic image and either the intensity of the light or the time of exposure. If we halve the former and double the latter, we do not get the same density of the image, but another which depends on the particular plate used. The grain of a plate also scatters light, and the actual size of the

image thus depends on the exposure and the intensity of the light. We were early compelled to conclude that accurate measurements of intensity by a photographic method involve the necessity of an equal exposure on the same plate for all the sources of light to be compared, and the method to be described satisfies this necessity.

The spectrograph for producing and photographing the lines of a spectrum is set up in the usual way, which requires no description. A wedge of neutral-tinted glass, cemented to another of clear glass so as to form a plane parallel plate, is mounted in front of the slit. The image of the slit formed by light of any wave-length is thus attenuated towards the part of the slit opposite the thick end of the wedge, where the absorption of light is greatest, and the image ceases to be strong enough to affect the plate beyond a certain specific height, which depends on the original intensity, in the beam from the source, of this particular wave-length.

The photograph thus consists not of the usual spectrum with all lines or slit-images of the same length, but of a spectrum in which all the lines are cut down to specific heights depending on the original intensities, and thus it gives a simultaneous record of all the intensities in the spectrum at any one instant. All spectrum lines have a breadth, due to the Doppler effect of the atomic motions in the kinetic theory, and to other agencies. The shape of one of the truncated lines depends on the original law of intensity across the line, and they may be wedge-shaped, or bounded by a more or less rounded curve, from the nature of which, if the boundary can be sharply defined, we can deduce mathematically the law of intensity across the original line. Sharp changes of intensity, such as occur when the line has several close components overlapping one another, are detected as peaks or kinks in this bounding curve. The original photograph can be enlarged with considerable magnifying power, and if the bounding curve on this enlargement is sharply defined, we can obtain its mathematical shape very accurately, and deduce an estimate of the intensity in any part of the line with a great degree of precision. We have been able to show that in most of our experiments such accuracy as 1 part in 100 has been reached, and it could readily be increased, if desired, by the use of greater magnification of the original photograph.

The determination of the exact boundary of a patch of dark on a white ground is a matter in which "personal equation" is important. We overcame this difficulty by enlarging positives, prepared from the negatives, on to bromide paper through a ruled "process" screen. The resulting photograph consists in this way of an assemblage of very minute dots, fading away towards the boundary into invisibility. It is a simple matter to prick out the last dots visible all round the contour, and in this way personal equation can apparently be entirely eliminated. We adopted usually about 100 dots to the inch on the final photograph. If comparisons of different lines with one another are required, only the central heights of the figures are necessary, and the topmost dot can be seen at once.

PARA-AMINO-CARVACROL—A NEW DEVELOPER.

[A communication from the Colour Laboratory of the United States Bureau of Chemistry describes the preparation of a new photographic developer having a constitution indicated by the above name. The new developer is a derivative of cymene, and its preparation has been worked out in view of the possibility of abundant sources of carvacrol prepared from cymene. We are indebted to the United States Bureau of Chemistry for this communication, which had previously been published in the "Journal of Industrial and Engineering Chemistry," May, 1919.—Eds. "B.J."]

For some time this laboratory has been engaged in a study of cymene and its derivatives, with the idea not only of preparing new derivatives of cymene, but also improving the methods of preparation of those already known and the development of their possible commercial application.

Two of the more extensively used photographic developers are *p*-aminophenol and quinol (hydroquinone). Similar substances can be prepared from cymene, and are described in the literature, but

(1) "Para Cymene. 1-Nitration, Mononitrocymene," "Journal of Industrial and Engineering Chemistry," 10 (1918), 453.

their commercial applications in photography have apparently not been investigated. Both *p*-amino-carvacrol and thymoquinol can be obtained from carvacrol. The preparation of *p*-amino-carvacrol is relatively simple, and a fairly good yield is secured.

The patent recently granted to McKee² on the preparation of carvacrol from cymene seems to make possible the development of an abundant source of supply of this phenol, which hitherto was prepared only in small amounts.

The process of McKee² involves the sulphonation of cymene by a subsequent alkaline fusion of the sulphonic acid. The preparation of a phenol on a small laboratory scale by such a method is usually not very satisfactory because of the poor yield from the alkaline fusion. The writer has found that a yield of 85 to 90 per cent. of carvacrol can be obtained by diazotising aminocymene, dropping the cold diazo solution into dilute sulphuric acid and simultaneously steam-distilling. This is a very satisfactory laboratory method for the preparation of carvacrol. The 2-aminocymene can be obtained in good yields by a method described in the first paper on *p*-cymene.

p-AMINOCARVACROL.

Tests of this compound showed it to be a very promising photographic developer.⁴ Comparisons of monomethyl *p*-aminophenol (commercially known as metol), *p*-aminophenol, and *p*-aminocresol with *p*-aminocarvacrol were so favourable to the last-named as to warrant a detailed investigation of its properties. The preliminary results indicate that *p*-aminocarvacrol is more satisfactory than *p*-aminophenol, but not quite so good as *p*-aminocresol or "metol," so far as lasting quality of the bath is concerned, but equally good with respect to quality of tones secured in the finished prints.

METHOD OF PREPARATION—*p*-AMINOCARVACROL.

was prepared by reducing *p*-nitrosocarvacrol by means of ammonium sulphide. For the laboratory preparation of *p*-nitrosocarvacrol the method of Klages⁵ is quite satisfactory. The following description is essentially the procedure of Klages, with slight modifications.

Ten grams of carvacrol are dissolved in 40 g. of alcohol, saturated with hydrochloric acid gas at 0°. To the cooled solution add an aqueous solution of 5 g. of sodium nitrite in 10 cc. of water. Before addition, the nitrite solution is diluted with an equal volume of alcohol. In a few minutes the solution becomes a pasty mass. This is diluted with water, filtered and washed. The crude nitrosocarvacrol thus obtained is not further purified but used in this form.

REDUCTION.—The crude nitrosocarvacrol is dissolved in about 10 times its weight of 10 per cent. ammonia and filtered from the tar. A rapid stream of hydrogen sulphide is passed into the ammoniacal solution and the aminocarvacrol is precipitated as practically colourless leaves. The solution is then cooled and filtered, the precipitate dried with suction, washed with cold water, and dried in a vacuum desiccator over sulphuric acid. In case it is necessary, the aminocarvacrol can be recrystallised by boiling with hot water to which animal charcoal has been added, filtering and cooling the solution.

To prepare the hydrochloride, which is much more soluble in water than the free base, the aminocarvacrol is suspended in a small amount of water and about the theoretical amount of hydrochloric acid added. The solution is heated and filtered while hot.

(2) U.S. Patent 1,265,800, May 14, 1918.

(3) "Journal of Industrial and Engineering Chemistry," 10 (1918), 982.

(4) Tests were made by H. A. Piper, of the Science and Research Department Bureau of Aircraft Production, since the photographic research of that organization was handled in this laboratory.

(5) "Biechter," 32 (1889), 1518.

To the hot solution concentrated hydrochloric acid is added until a precipitate begins to form. When the crystallisation is completed by cooling the solution, the hydrochloride is removed by filtration and dried in *vacuo* at 75°.

From 10 g. of carvacrol about 5 g. of aminocarvacrol in quite a pure condition were usually obtained.

sulphonating carvacrol and oxidising the sulphonic acid by means of potassium bichromate. The quinone thus produced was reduced by means of sulphur dioxide. The yields were very poor, and since this compound, from preliminary determination, shows no advantage over ordinary quinol, work along this line was not further prosecuted.

p-Aminothymol was also prepared, but this base did not seem to be so satisfactory a developer as the corresponding carvacrol derivative. One disadvantage is the relatively low solubility of the free base in water.

SUMMARY.

p-Aminocarvacrol is a very satisfactory photographic developer, and its preparation and use for such a purpose would furnish a means of using a portion of the large amount of *p*-cymene which is not being utilised at present.

HERBERT A. LUBS.

Exhibitions.

PHOTOGRAPHS BY MR. WARD MUIR.

THE exhibition of "straight" photographs by Mr. Ward Muir which is being held at the London Camera Club during the present month is, so to say, a kind of mission, though Mr. Ward Muir suggests rather than defines his point of view. His text, according to the catalogue, is "Photography deals with facts. Point your camera at a beautiful fact and you get a beautiful photograph." In supplement to this dictum it is stated that the photographs are all direct prints or enlargements from unretouched negatives. The seventy exhibits show a variety of treatment and effect which will certainly be welcomed by those, like ourselves, who have long contended that photography loses much of its intrinsic quality as an artistic medium when it allies itself with non-photographic methods. Nevertheless, we cannot help feeling that without going to the extremes which have been adopted by many pictorial workers, a capable critic and self-critic as Mr. Ward Muir is would have produced from these same negatives an exhibition which artistically would have been more satisfying had he not elected to follow rigidly the path of "straight photography." In eschewing "control" of any kind whatever we think Mr. Ward Muir has only shown that he has lost something by doing so. While using such means as may reasonably be said to be photographically legitimate, he would have expressed his text in his photographs no less forcibly, for as we interpret the dictum which we have quoted he is seeking to get photographers to realise that if they can see a beautiful fact, more than half the battle in the making of a photograph with some claim to artistic quality has been won. Not all of it, however, as we think; and the exhibition is also incidentally a demonstration of that. But whatever one may think of these considerations the collection is one which is bound to be of the very greatest interest to the amateur photographer who must surely envy Mr. Ward Muir both his gift of perceiving lines and pattern in landscape, and even in the surroundings of manufactories, and his accomplished technique in rendering delicate effects of tone and lighting. The exhibition is open daily except Sundays from 10 a.m. to 5 p.m. at the Camera Club, 17, John Street, Adelphi, London, W.C.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, August 17 to 30.

SELF PORTRAITURE.—No. 20,340. Self-photographic attachment for hand cameras. E. J. Davis and S. Dronsfield.

FILM SPOOLS.—No. 20,519. Photographic roll-film spools. M. Niell.

CINEMATOGRAPHY.—No. 20,640. Cinematograph apparatus. H. H. and S. H. Moon.

ARC LAMPS.—No. 21,037. Arc lamps for photography. B. J. Hall.

CINEMATOGRAPHY.—Nos. 20,997 and 21,396. Cinematograph apparatus. Barr and Stroud and J. W. French.

CINEMATOGRAPHY.—No. 20,998. Operating film in cinematograph apparatus. Barr and Stroud and J. W. French.

CINEMATOGRAPHY.—No. 20,899. Apparatus for photographing or projecting moving pictures. C. and H. C. Beck.

CINEMATOGRAPHY.—No. 21,133. Cinematographs. H. Grimshaw.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 6d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

AERIAL STEREOSCOPIC PHOTOGRAPHY.—No. 128,022 (June 26, 1918).

According to the invention, the camera is provided with a blind corresponding to that of the ordinary focal plane shutter, but having in place of the usual slit or aperture which extends right across the plate two slits, one extending from near the edge of the plate to a point approximately at the centre thereof, and the other of a similar length but extending from the centre to near the other edge of the plate. These two slits are separated from each other by a length of the blind sufficient, according to the speed of the spring roller which causes the travel of the blind, to provide the necessary time interval between the one exposure and the other.

If necessary, any suitable stop mechanism may be provided to cause the blind to pause in its travel relatively to the plate between the exposure caused by one slit and that brought about by the other.

Any well-known mechanism may be used for determining and regulating the time interval between the exposures, and such mechanism may be made dependent upon the speed of the aero-plane if desired.

In some cases it may be possible to make the interval between the two exposures depend simply upon the length of the blind separating the two slits, but usually it is more convenient to employ some form of pause or stop mechanism in connection with the blind roller.—Douglas Arthur English, Captain, Royal Air Force, Instructional Officer, School of Photography, South Farnborough, Hampshire.

CAMERAS WITH MECHANICAL PLATE-CHANGING.—No. 128,662

(August 29, 1917).—The invention relates to magazine plate-holding and plate-changing apparatus having magazines for the unexposed plates and for the exposed plates, and a sliding frame by which the plates are transferred from one magazine to the other, as described in Patent 11,651, 1915. A clock-work, spring, or other motor is provided so that, on release of the shutter, or on starting the motor, exposure is effected, the plate is transferred, and the shutter is re-set.

As shown in fig. 1, a spring motor, B, is connected through a train of wheels with a wheel, b, which is linked to and rocks a quadrant, D, engaging a compound pinion, a', a'', in gear with a

affording the subject. The information prepared in this sheet should be used in the usual manner. Price Three Shillings Sixpence.

Trade Names and Marks.

MARKS PLACED ON THE REGISTER

The following marks have been placed on the register—

Messrs. No. 56178 Photographers chemical Jellies and Sun Manufacturing Company Limited, 23, Cross Street, Finsbury, London, E.C. 4, the chemical manufacturers.

APPLICATIONS FOR REGISTRATION

Drinks—No. 56178 Chemical substances used in manufacturing photography etc. The British Drug House Ltd, 25, Abchurch Lane, London, E.C. 4, the chemical manufacturers.

CATALOGUES AND TRADE NOTICES

Wax & Resin Lenses—A 24 page booklet just issued by Messrs. Ross Ltd, Optical Works, Chapman House, London, E.C. 4, describes in an interesting way the various features of these class types of Resin lens, namely, the Lycopodium, and Polystyrene, and it mentions a particular of these instruments. The booklet which is sent free on application contains a large number of reproductions of photographs taken with the lenses.

September 13 to October 11, London, Salon of Photography, 10, St. Paul's Church, London, W.C. 1.

October 13 to November 20, Royal Photographic Society, Entrance close September 18 (winter), September 20 (hand), Secretary, J. McLetchie, 15, Russell Square, W.C. 1.

News and Notes.

With Mr. Hanks, late of Gresham Street, kindly address the Editors, who have a communication for him.

Mr. A. Carrivan, formerly manager of the professional department of Messrs. Kodak Ltd., has joined the staff of Messrs. Houghton Ltd., and will represent their professional department in the Midlands, South Wales, and West of England.

1,000 TRAVELLING DARK ROOMS according to a recent report in the "Times," are among the surplus R.A.F. material which has accumulated at the R.A.F. storage depot at Fallowfield, Middlesex.

LIGHT FOR RETOUCHING.

To the Editors.

Gentlemen,—The arrangement for modifying the light for retouching, explained in the "B.J." of August 29, seems very elaborate, and rather unnecessary. In the days when I did a good deal of retouching I found it best to avoid any arrangement which allowed any light, however diffused, to fall directly on the negative, as it was always very trying to the eyes, and I maintain that retouching ought not to produce eye-strain if the negative is properly illuminated. I have often retouched till long past midnight without getting my eyes tired. The arrangement I have always used, whether the source of light was paraffin lamp, incandescent gas, electric or daylight, allowed no light to fall directly on the negative, but was all sent upward through the negative by reflection from a sheet of white paper, or if the negative was extremely dense a piece of matt sheet aluminium was used instead.

Eye-strain in retouching is caused by trying to see every stroke made by the pencil. I believe it may be almost entirely avoided by working at such a distance that each touch is not seen but only the general effect, working just as an artist does when he "stipples" in water-colour or miniature painting.

Many retouching desks are not sufficiently upright; the slope of the desk should not be less than 60 degs. This will be found more restful and healthy, and will not cause the worker to stoop. This was the angle of the desks used by the mediæval writers, who spent their lives writing at a time when writing was a fine art. I often wonder that men who spend their days "pen pushing" do not use a desk with a steep slope; they would get far less indigestion and have straighter backs.—Yours faithfully,

RETOUCHER.

EYE-GLASS FOCUSING MAGNIFIERS.

To the Editors.

Gentlemen,—Some time ago in "Ex Cathedra" some hints were given about a magnifying glass for focussing, and it was suggested that it should be attached to the camera. It reminds me of a friend of mine, a process-worker, who always had his magnifier tied to his working coat with a piece of string; but that arrangement would scarcely suit the portrait operator, whose appearance should be fairly respectable. A far better arrangement than the usual eye-piece, which can be used with only one eye, and also needs a hand to hold it, is a pair of eye-glasses fitted with magnifying lenses to fit the wearer's sight; they will be found extremely useful for many purposes. But only the lower half should magnify; the upper half of the rims should be filled with lenses to suit the wearer's ordinary sight, so that he may see the sitter or object to be photographed through the upper half of the frame, and look through the lower half at the image on the focussing screen. The arrangement is known as a Franklin lens, and can be supplied by most opticians, and the people who need a magnifier for focussing usually need spectacles or eye-glasses for reading, and will find no difficulty in using a pair of extra strong ones for focussing, and they will be found far better for the work than a single glass, which has to be held in the hand and moved here and there over the focussing screen. Of course, such glasses should be worn only when focussing or examining any object where a magnifier is necessary. They should, of course, be carried in the pocket when not in use, and not left lying about.

It is best to get the optician who supplies these very strong glasses to test each eye separately, as probably no living person possesses a pair of eyes of equal focus, like a stereoscope.

The optician must be shown how much magnification is necessary, as, of course, the amount varies with every individual, and it will be found that every year or two more powerful lenses become necessary. But some people are so vain of their youthful looks that they will go on straining their eyes for years rather than admit that they need "glasses." Nothing could be greater folly for a photographer, whose living depends largely on his eye-sight.

These Franklin lenses are very useful for ordinary purposes, and will save carrying two pairs of spectacles and having to change from one to the other when a different focus is wanted.—Yours faithfully,

BI-FOCAL.

THE EYE-LEVEL REFLEX.

To the Editors.

Gentlemen,—Poor much-criticised reflex, most beloved of my possessions, why must you always be condemned for waist-level use? Never since purchasing have I used you at waist level. At scale focussing I am lost, being poor at judging distance, but that is one of the things which never trouble me now I can always use my reflex at any time. The enclosed photograph shows the machine open ready for use. I always focus up to the moment of exposure; then, looking down into the mirror with an half-glance along the top of the camera at my subject, I firmly press the hood against my forehead, pressing my elbows firmly into my sides, making my exposure. No use for *Yankee periscope* here; this can always be used at eye level. I am much surprised some enterprising firm does not make a reflex on these lines. I do not say mine is an original idea, but I have never seen another one in use. I purchased an ordinary Planex

reflex, took off the look-down hood, which was utterly useless for my work, and fixed the adapter containing a mirror at an angle to the focussing screen, and it has added pounds in value to my machine. Furthermore, the reflex can be used much steadier in the position I have adopted than at waist level. I have exposed at 1/4 sec. and enlarged from the same without showing the least movement. Of course, the object is reversed in the mirror (that is, upside down), but to a camera man that does not make the slightest difference. Don't wait for the Yankee dodges, which only add weight to what is already condemned for bulk. The adapter here shown, when not in use, folds perfectly flat, and lies flat on the top of the machine, taking no more room than the ordinary folding hood.

The above article may prove of interest to many of your readers (along with the photograph). It is the machine I have in use, has been given a severe test under all conditions, and has never failed me yet. The idea is quite practical and well worth adopting. I do not like the reflex-condemning when I know the waist-level idea is all a fallacy.—Yours sincerely,

A. PALFREYMAN.

3, Chapel Lane, Attercliffe, Sheffield, Sept. 1, 1919.

THE BELITSKI REDUCER FOR NEGATIVES AND BROMIDES.

To the Editors.

Gentlemen,—The articles by "Practicus" are always good and helpful, and as a rule I agree with what he says, but for once I find my experience is quite contrary to his. In recommending Farmer's reducer he tells us if we want to clear up the shadows of a negative to use the reducer so strong that it acts very quickly and reduces the shadows before it touches the denser parts; and by using it very dilute it will reduce the high-lights before the shadows are touched by it.

My experience is exactly contrary, and when I wished to reduce a hard negative I used it so strong that it acted very rapidly, so rapidly in fact that the dish had to be violently rocked to ensure even action over the whole of the plate, and I always kept one finger under a corner of the negative so that I could snatch it out of the reducer and hold it under a strong flow of water from the tap, which was kept running during the whole time, so that not a second should be lost in turning on the water. The whole time of reduction would not exceed ten seconds on many occasions. But if I wished to reduce the shadows without affecting the high-lights I used it so dilute that the operation would take ten minutes or longer. I have quite given up using this reducer, except when I wish to make a negative more brilliant to put a little sparkle into a lantern slide which is maddy.

For the last year or two I have used another reducer for softening contrast; it is known as Belitski's. It works very evenly, attacking the dense parts first, or it appears to do so, and only reducing the shadows when a great amount of reduction is attempted. It is the best reducer of bromide prints I have ever used. It will keep in good condition for months in the dark room, and is always ready for use, and may be used repeatedly till exhausted.

It is made by dissolving potassium ferric oxalate 22 gra., and sodium sulphite 18 gra., in water 1 oz. When dissolved a blood-red solution is formed. To this are added a few crystals of oxalic acid. As soon as the red solution turns green it is poured off the crystals, which may be thrown away. Finally, hypo, 120 gra. in $\frac{1}{2}$ oz. of water, is added, and the reducer is ready for use. Negatives may be put into it as soon as they are fixed, unless they have been developed with pyro, and the fixing-bath discoloured with pyro. In such cases it is advisable to wash the negative before reducing, to avoid an ink-coloured stain formed by pyro still remaining in the film and the iron salt in the reducer. As a matter of fact, ink is really made by mixing gallic and iron compounds. As the solution keeps indefinitely in the dark-room, it is convenient to make up fifty or more ounces at a time, and it is then always ready to reduce either negatives or prints. I have not tried it for print-out silver papers, but I should think it would work equally well with them. It is convenient to make up this reducer with a smaller proportion of water when making a stock solution, as it works rather slowly for negatives if used at the strength given above, but it should be diluted considerably for bromide prints. It will not reduce toned bromides. The only solution that will do this that I know of is the iodine-cyanide given by "Practicus," which, however, I make up in a simpler way by adding a few drops of strong tincture of iodine (which can be obtained at any chemist's) to a solution of potassium cyanide.

Ammonium persulphate has never been a favourite of mine, as it has always been so erratic in my hands, and has more than once ruined a negative, and the Belitski reducer has proved a good substitute. This latter is most useful when making a series of negatives on panchromatic plates, for instance, when it seems almost impossible to secure even density, in spite of all precautions in using exposure meters, standard developers, and timing development; the density of the negatives will persist in coming of different densities. It is then that this reducer is so useful, because the denser ones can be brought down gradually to the proper density without upsetting the proper gradation. I think that professional photographers would find it a most useful addition to the dark-room solutions.—Yours faithfully,

HAROLD BAKER.

Answers to Correspondents.

SPECIAL NOTICE.

In consequence of general reduced supplies of paper, as the result of prohibition of the importation of much wood pulp and grass, a smaller space will be available until further notice for replies to correspondents.

Moreover, we will answer by post if stamped and addressed envelope is enclosed for reply: 5-cent. International Coupon, from readers abroad.

The full questions and answers will be printed only in the case of inquiries of general interest.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

F. R. I.—You can get a new blind fitted to the Goerz Anschutz camera by Mr. R. E. Peeling, 4/6, Holborn Circus, London, E.C.4.

R. M.—Formaline is a 40 per cent. solution of formaldehyde in water. As regards formulæ for hardening-fixing baths containing formaline, the best reply we can make to you is to refer you to a paper on this subject in the "B.J." of November 2, 1917, which probably our publishers can still supply, price 4½d.

N. E. M.—A little book which our publishers issue, "Commercial Photography," price 1s. 2d. post free, is actually the only manual which deals with such work as an engineering photographer is called upon to do. No doubt the hints in it would be of service to you.

S. A.—We do not think the two postcards are photographs, in all probability they are lithographs, for when examined under a magnifier the image shows a characteristic lithographic grain. Photographically it would be difficult to match them except very crudely, but you can easily see how near you can get to them by using the Bertha stains of the Vanguard Manufacturing Company, Maidenhead, which are prepared and sold for obtaining this kind of effect.

A. F. C.—So far as we understand your letter, any agreement which you have made with your landlord is not upset in any way by your position under the Retail Businesses (Licensing) Order. If you have made an agreement for the lease of premises and you subsequently find that you cannot get a licence to carry on the business we think there is no doubt whatever that the agreement with your landlord still holds good. We imagine this is what you are asking us.

A. M.—For copying outdoors the best arrangement you can have is a kind of funnel-shaped tent made of muslin and open at each end. One end is pushed up right against the easel, whilst the camera is pointed into the other end. By this arrangement you get a very efficient diffused light which will show the minimum of grain in an original. You can easily adjust it to changes such as the sun coming out by having one or two thicknesses of muslin laid on the tent. "Commercial Photography," issued by our publishers, describes this arrangement further.

4 E.—In enlarging from 12 x 10 negatives you require a lens which will cover a 12 x 10 plate, which means a 14 in. lens of, say, f 6.8 aperture, or, say, a 10 in. lens if of the wide-angle type and of f/16 aperture. The latter may make enlarging unduly slow if you are working by artificial light, and also even by daylight in the case of dense negatives or poor daylight. On the other hand, the 14 in. lens necessarily calls for more space between the lens and the enlarging easel if you are making enlargements on any considerable scale. Of the two, however, we should say that a 14 in. lens of about f 6.8 is by far the better choice.

E. V.—We suppose it is a condenser enlarger, in which case the best electric light is a small arc lamp such as is supplied by the Westminster Engineering Co., Victoria Road, Willesden, N.W. The alternative is a half-watt lamp of the focus type, that is with the filament brought to a small cluster. We are by no means sure that these are now obtainable again. You should apply to the General Electric Co., Ltd., 67, Queen Victoria Street, London, E.C. If you have dense negatives to deal with at times, especially on a great scale of enlargement, you had far better choose the arc. With a focus lamp you are pretty certain to require to diffuse the light with a ground-glass screen placed as near to the lamp as can be done. Even though this may be necessary with an arc lamp, the much greater actinic intensity of the latter allows of exposures still being conveniently short under unfavourable conditions.

S. T.—If your sulphide bath was in good condition there is nothing in the formula to account for the bad tones. It would be worth while to make up fresh sulphide stock if further prints are defective in this respect. Apart from this, one of the most common causes of weak prints and bad colour is too rapid (that is, too superficial) development of the black print. It is a necessary rule for the best sepia results, as regards colour and depth, to expose the bromide paper only for such time that it can be developed for three or, better, four minutes without becoming too dark. In this way you get a more solid deposit in the black prints with corresponding benefit to the sepia tone.

F. M.—I. Under the Retail Businesses (Licensing) Order you require to obtain a licence to open a new studio. The office to which you should apply is 5a, Union Street, Bristol. If you do not trade in your own name, you also require to register under the Business Names Act. For this you should apply for a form to the Registrar of Business Names, 39, Russell Square, London, W.C. 2. Prints mounted with the gelatine mountant, formula for which is given in the "Almanac," should not suffer from impermanence in any way. We used these mountants years ago, and have never noticed any results of fading, and are quite sure that, at any rate, development prints would show none from this cause. For prints of more delicate image, such as P.O.P. there is no mountant, so far as permanence is concerned, to equal that made with starch.

H. C.—With an $f/4.5$ or even $f/6$ lens and a focal-plane shutter which will give such slower speeds as $1/25$ th or $1/50$ th of a second under-exposure ought not to be an inseparable feature. However, if plates are regularly under-exposed, we are afraid there is no really satisfactory remedy for it by development. Personally we should use pyro-metol for such cases, although, unless you are ready to use it fairly weak and are careful not to over-develop, you can easily get negatives which are hopelessly hard. Certainly you can use the developer warmer, up to 70 or perhaps 80 degs., if the plate will stand it. On these lines you might find the hardening solution sold as the "Tropical" by Messrs. Johnson and Sons, 23, Cross Street, Finsbury, London, E.C., of service to you, but you are always on the limit of fogging the plate in warming the developer up. Without knowing what subjects you have in mind, we think that you must be giving unnecessarily short exposures.

D. K.—Twelve feet square is a very small room even for ordinary portraiture, that is of single figures, and almost impossible for groups even of two or three people. You are already finding that out in using your present lens, which, probably, if sold with a half-plate camera, is about 8 or 9 ins. focal length. In order to get in a full-length figure on the half-plate you would want a lens of only about 6-in. focus, which, to cover a half-plate, would have to be one of the slow wide-angle type. Therefore you are between the devil and the deep sea. You must either get more space or be content with either part of the figure on the plate or the use of a wide-angle lens. Without knowing more of your circumstances, we should say your best course would be to confine yourself to three-quarter length figures or head-and-shoulder portraits, in making which you will probably find that the focal length of your lens is about right for the dimensions of the room, although very likely it is not of the large aperture, which is almost a necessity in indoor portraiture.

D. M. C.—Generally speaking for a very long stay in a tropical climate an all-metal camera is preferable or else a tropical wooden model of teak specially made without any glueing. A Thornton Pickard shutter is a good choice since you could easily repair it. You should take a duplicate. A portrait lens would be a very unsuitable one for the work you have in mind, we should advise an ordinary R.R. of about 8 to 9 inches focal length for a half-plate camera or a 5 or 6 inches R.R. if you choose quarter-plate. Bromide paper also is the best material as regards keeping quality. You should have it packed in metal boxes. Unless you are going somewhere altogether away from civilisation, we should think you would do better to buy paper and plates from the supply houses in India. For film hardening take a supply of Ilford "Tropical" hardener obtainable from Messrs. Johnson and Sons, 23, Cross Street, Finsbury, London, E.C.3. Solid hypo will keep and so will a plain hypo solution, or, preferably, hypo with a little meta-bisulphite in it, for a reasonable time.

A. M.—I. It should not be necessary to stop a lens further than $f/16$ or, at the most, $f/22$ for copying work. A decent R.R. ought to work satisfactorily at $f/16$, supposing that the focal length is about $1\frac{1}{2}$ times the length of the long side of the plate. You must remember also that when the distance between lens and plate is increased appreciably beyond the focal length of the lens, the stop number becomes greater and exposure requires to be correspondingly increased. There is a table in the "Almanac" which provides a guide to this increase of exposure, but you must not reckon your stop as $f/16$ or $f/22$, or whatever you choose to set it to, at all extensions of camera. 2. To make the best of the job rub the stick of Indian ink with a little water in a circular palette or saucer. This is a slow job, but it makes the best mixture of the ink. When you have a creamy paste through rubbing the ink and water you require to add a little syrupy gum and enough methylated spirit to make the backing mixture dry more quickly. Your method is, however, a very slow way of making the backing, you had far better buy the caramel prepared specially for making backing by Messrs. Lichenstein, of Silvertown, London, E., and purchasable through any of the large dealers in photographic chemicals.

Line Advertisements. Charges for Insertion.

Since advertisements cannot be inserted until fully and correctly prepaid, senders of line announcements are asked to bear in mind the scale of charges. They will thus save themselves delay in the publication of their announcements. A Schedule by which an advertisement can be correctly priced will be sent on request.

Net Prepaid Line Advertisements.

12 words or less	1/-
Extra words	1d. per word.
(No reduction for a series.)				

Special Note. Box Number Advertisements.

"Box No." and office address charged as 6 words.
For forwarding replies add ... 6d. per insertion for each adv't.
If replies are called for this latter charge is not made.

Advertisements cannot be inserted until fully and correctly prepaid.
Orders to repeat an advertisement must be accompanied by the advertisement as previously printed.
Advertisements are not accepted over the telephone or by telegram.
The latest time for receiving small line advertisements is 12 o'clock (noon) on Wednesdays for the current week's issue.
Displayed Adv'ts should reach the Publishers on Monday morning.
The insertion of an Advertisement in any definite issue cannot be guaranteed.

SUMMARY.

The exhibition of the London Salon of Photography, which opened at the Galleries of the Royal Society of Painters in Water-Colours, 5a, Pall Mall East, on Saturday last, contains a goodly proportion of portraiture and figure-study work both by professional and amateur photographers. This work is reviewed in an article on page 544. Next week we shall publish some personal impressions of the exhibition by Mr. F. C. Tilney, who will deal also with the landscape work at the exhibition.

In his article this week "Practicus" deals with the making and supply of miniatures, including in this category not only the hand-painted miniatures on ivory, but also the cheaper varieties of celluloid-faced miniature portrait, as well as the ceramic enamels. (P. 550.)

A paper by Mr. Frank B. Howe before the Californian Camera Club has dealt with some of the lesser-known branches of enlarging, and will no doubt provide much suggestion and instruction in this field, the appropriate season for which is now opening. (P. 546.)

In a leading article we endeavour to set before intending patentees a statement of the real value of the rights which they acquire when granted Royal Letters Patent. We also refer to one or two of the formalities to be observed in taking out a patent, of which there is undoubtedly much misconception. (P. 542.)

Particulars of a new description of flash lamp, namely, one producing the flash by the electric volatilisation of a metal, are contained in a recent patent specification. (P. 553.)

M. L. P. Clerc, in a note on the Desalme method of sepia toning with polysulphide, records his experience that the process is applicable to commercial papers in somewhat the same erratic manner as liver of sulphur. (P. 551.)

A paragraph in "Photo-Mechanical Notes" contains a suggestion as to the avoidance of moiré pattern in half-tone. (P. 552.)

A formula for putting labels on bottles permanently and the suggestion of a waterproof paint suitable for dishes and tanks are mentioned in "Assistants' Notes." (P. 552.)

Reproduction fees, photo-lithography, the Retail Businesses Licensing Order, refixing of prints, and the making of a lens hood are the subject of brief replies to correspondents. (P. 555.)

Some of the things which may and may not be done in the use of bought specimens are the subject of a paragraph on page 542.

The preservative action of sulphite in a working developer is considerably reduced, with the lapse of time, by mixing the sulphite with the alkali, such as sodium carbonate in the separate solution of the latter. (P. 541.)

Very weak solution of potassium permanganate serves as a readily applied test for the presence of hypo in prints or negatives. (P. 541.)

EX CATHEDRA.

Sulphite and Alkali. A point which recently came under our notice may be of interest to some of the many photographers who use pyro-soda developers. Our friend was complaining of the yellow tinge which pervaded all his negatives, and asked us to test a sample of the sulphite which he was using as a preservative. This appeared to be quite satisfactory, and the quantity which he was using should have been ample to prevent any discolouration of the solution. On investigating his methods we found that he was making rather concentrated stock solutions in considerable quantities, enough, say, to last a month or two at a time. When freshly mixed the developer was quite satisfactory, but it quickly deteriorated, in spite of the fact that he was also using acid bisulphite in the pyro solution. We found, however, that he was mixing at least half the prescribed quantity of sulphite with the carbonate of soda, being under the impression that the salt would crystallise out if it were all used for the pyro solution. Upon making a test with dry pyro and the carbonate and sulphite solution alone it appeared as if no sulphite were present, although three times the weight of the pyro was actually present. It would appear, therefore, that the alkali had practically destroyed the action of the sulphite, which had been kept in solution with it. On making fresh stock with all the sulphite in the pyro solution the trouble disappeared, and the developer worked cleanly to the end.

* * *

Print and Plate Washing. If it be necessary to wash either negatives or prints for the minimum of time or the smallest quantity of water consistent with safety some means of testing the efficacy of the washing must be employed. For this purpose nothing is better or simpler than the well-known permanganate test, which indicates by colour the presence of a very small quantity of hypo. This may be conveniently done by making a stock solution containing one grain of permanganate of potash and ten grains of carbonate of potash to a pint of water. This will be of a rose colour, and will remain so for a long enough time if kept well stoppered. To use it, about an ounce of drippings from plates or prints, as taken from the washer, is collected in a clean measure, and a few drops of the permanganate solution added. If any appreciable quantity of hypo is present the pinkness will disappear almost instantaneously; if only a trace remains, it may take two or three minutes to discolour. It is a good plan, until accustomed to the test, to have a check in the form of a glass of clean water to which the same amount of permanganate is added as to the washing water. If this also decolorizes or turns brown it is a sign that the water supply is contaminated with organic matter. In that case a further test should be made with distilled water.

Buried Knowledge.

In the course of a year many items of interest to the individual photographer appear in the weekly issues of the photographic press, but in the rush of work they are lost sight of, and when occasion arises to refer to them they are not forthcoming. We do not think that many people preserve—much less bind—photographic periodicals, and the result is that when a difficulty arises there is no course open but to address a query to the editor. This, of course, elicits a reply which is necessarily brief, and although the inquirer may be referred to a full discussion of his problem, the issue containing the article may have run out of print. To obviate this it is an excellent plan to adopt a simple method of filing such articles as the reader may feel interested in. A cheap and easy system is to procure a packet of strong manilla envelopes about 7 by 5 inches. On the outside of each is written a different subject, such as Bromide Printing, Intensifiers, Lens Matters, and so on, the whole being enclosed in any convenient box. It is now easy to cut out any article or paragraph, and to file it away for future reference. Small paragraphs should be pasted upon a larger piece of paper to avoid loss. Naturally, the file need not be exclusively photographic, but may contain many useful wrinkles and recipes for matters of household interest appearing in the daily and weekly newspapers. The file is better than a scrapbook as no pasting is required, and any required degree of classification can be arranged.

* * *

Print Surfaces.

Many photographers place much of their best work at a decided disadvantage through neglecting to pay more attention to the surface of the printing medium. Years ago there was little or no choice allowed among the printing papers that were commercially available, but at the present time the reverse is the case. We find one of the best-known bromide paper manufacturers listing over thirty different grades and surfaces of paper, and such a selection of surface is of immense value to the discriminating artistic photographer in presenting his work to its best advantage. In ordinary portraiture the selection of the surface of the printing paper becomes of the first importance. For a dainty sketch portrait of a feminine sitter or a child there is nothing to equal a print on a smooth matt or cream base paper, while in the case of large head studies of elderly people a rough surface is decidedly pleasing, for it has the effect of breaking up rough patches of skin, of covering up much of the work of the retoucher, and of adding a texture to the print that is thoroughly in keeping with it. Moreover, as prints are nearly always of fair size, and are viewed from a distance, for such, a rough paper is in every way suited. Other examples could be cited, but enough has been said to show the photographer the real importance of discrimination in choosing the surface of his printing medium.

* * *

Bought Specimens.

The ethics of exhibiting specimens which have not been taken by the photographer who shows them were discussed a week or two ago, but it is difficult to say what can be done in a general way. On the other hand, the facts of a given case scarcely ever admit of doubt as to whether the display is reprehensible or not. The question is an old one, for a generation ago it was the custom for such specimens to be openly advertised for sale, some firms of good reputation being willing to supply showcases ready filled. As far as we can see, all that can be done is for the various associations of professional photographers to make it a condition of membership that the practice shall not be indulged in, and even then it is difficult to draw a line. Many enlarging firms will supply specimen pictures, often

at a reduced rate from their own stock negatives. In our opinion little harm is done by the use of purchased specimens, as the public quickly finds out that the work executed is not up to the samples shown, and the fate of the photographer is sealed. Again, what shall we say if, when a new style comes out, as in the case of sketch portraiture, anyone shows specimens made by a first-rate trade house, and afterwards supplies an inferior home-produced line? This is not uncommon, and we have often amused ourselves by picking out the trade specimens in a window show. A practice which cannot be too strongly reprehended is that of appropriating specimens sent by operators in answer to advertisements; this is neither more nor less than sheer robbery, which renders the offenders liable to prosecution.

SOME NOTES FOR INTENDING PATENTEES.

A TECHNICAL newspaper such as the BRITISH JOURNAL, like many others dealing with a subject which does not require a high degree of scientific study or technical training for its practice, is often called upon to give advice to its readers on protecting inventions, which they claim to have made, by taking out patents for them. As it is impossible to explain to individual inquirers at the requisite length some of the elementary matters connected with the taking out of a patent, we may turn aside for once from photographic topics and devote a few lines to putting forward a few essential facts which perhaps are not so widely realised as they should be. Unfortunately, it is not possible to refer such inquirers to text-books on the subject, for these latter are either comprehensive treatises on patent law, which it would take a lifetime to assimilate, or they are more or less informative manuals, issued, however, by patent agents, whose object is to encourage the inventor to get a patent granted for the invention.

Perhaps the first misconception, and the one most widely held, of the nature of a patent is that it is some kind of certificate or testimonial of the value of an invention. There are scores of people going about inwardly patting themselves on the back because they are the possessors of Royal Letters Patent, an impressive phrase which, however, means very little indeed. The real fact is that the Patent Office is a branch of the Board of Trade which, under the Patents Act, has very limited powers. It may, perhaps, be best described as a kind of glorified registry of the inventions which people claim to have made. It is a little more than this because it carries out a complex system of search among inventions which have previously been registered in its files in order to ascertain whether a given invention which it may be asked to register and to accept for protection by Royal Letters Patent has been so accepted and protected, in whole or in part, previously by somebody else. If it is found that there has been a prior invention, then the Office has the power to ask the later applicant to disclaim the previous invention and to show that his is something different from it. Moreover, if the applicant cannot or will not do this, the Office has the power to insert what is called a "reference"—that is, a mention of previously patented inventions which, in its opinion, are very closely allied to the later one. This "reference" is made in colourless official language without a trace of unpleasant suggestion in it, but in many cases such a reference is a condemnation of the novelty of the invention which might very well be put in forcible terms—say, those of Lord Fisher.

Apart from seeking to have an invention clearly described, this search among its records of previous inventions is practically all that the Patent Office troubles about. The invention may have been published before and over again in books or periodicals; on the face of it, it may be

an utterly ridiculous and impossible invention; or the means suggested for carrying it out may be manifestly absurd. So long as the patentee makes it clear what he really does mean, his "invention" cannot be objected to, and in the fullness of time it is accorded the dignity of Royal Letters Patent. These matters, efficiency, and real novelty are left to be thrashed out in the Law Courts. No doubt the reader has noticed in the prospectuses of industrial company flotations the importance which is laid upon the fact that a judicial decision has been given, in the course of litigation, on some patent which is an asset of the company. Failing that, the opinion of technical experts and counsel is sought by way of testimony to the value of the patent from the industrial and the legal standpoint. Many people, we are afraid, neglect these aspects of a patent and imagine, when the specification has been accepted and the patent has been sealed, that their difficulties are at an end. Very often they are only beginning.

There is really no reason why intending patentees should be ignorant of the limited value which a patent has until something has happened to establish its value. If they would study the "Instructions to Applicants for Patents," which is obtainable free from the Patent Office, 25, Southampton Buildings, London, W.C., they would detect for themselves the very small grounds on which the application for a patent can be refused. These grounds are of two kinds: (1) Certain things are excluded from protection by patent; and (2) refusal to comply with the formalities of the Patent Office. Under (1) are excluded inventions which do not "realise or affect" some material product of a substantial character. In other words, an invention must deal with some thing or substance, and not merely an idea or scheme. There are, however, a whole host of inventions which may be said to represent schemes or ideas, but which nevertheless secure protection by patent by being associated with some tangible means for carrying them out. Again, patent protection is not granted to the very limited class of inventions in which it is proposed "to use, modify, or imitate natural conditions existing on the earth's surface, there being no invention as to the means or apparatus applied to these purposes." Also protection by patent can be refused in the case of inventions the use of which is contrary to law or morality. It will be seen that when one has allowed a very wide field for the exercise of refusal on these lines, the possibility of obtaining a patent for almost anything one can think of is very slightly affected. If one wants to obtain a patent for making developing dishes of chopped straw and glue, there is nothing to prevent one from getting it. Even in the event of some other genius within the last fifty years having taken out a patent for developing dishes of chopped straw and glue, we can still have ours either by claiming, for example, chopped oat straw instead of the other man's wheat straw or Russian glue instead of Scotch glue; or, without making these disclaimers, allowing reference to the previous specifications (of wheat straw and Scotch glue) being made by the Comptroller of Patents. Such a case as this, which does not exaggerate the circumstances of patents which are frequently granted at the present time, however silly it may sound, will perhaps serve to make clear the extremely problematical value of a patent even when all the formalities have been complied with.

A careful reading of the official "instructions," to which reference has already been made, will enable the intending patentee to follow the correct course in making or pursuing the application for a patent, but one or two other points may be mentioned. Application for a patent may be made in two forms, either by depositing a "provisional" specification, which is a general and brief description of the invention, or a "complete" specification, which is sup-

posed to be a description of the invention in its finished form. A "provisional" specification is provisional—that is, it requires to be replaced by the complete specification within six or, at the latest, seven months. During this period it protects the inventor in the sense that it establishes an earlier date for the invention than would very often have been possible if the inventor had to wait to work out his process or machine fully before making his application. At the same time it must be borne in mind that the acceptance of a provisional specification is of still smaller value than that of a "complete," for the reason that search for anticipation is not made in the case of provisional applications, but only when the complete description of the invention has been deposited at the Patent Office. It is, therefore, incorrect to suggest, as is sometimes done, that a provisional specification can be sealed. It is never sealed, but is either completed by the filing of the complete specification or is abandoned through the inventor thinking better of it in the six months' interval. Another point which leads many inexperienced patentees astray is the request on the official form of application for a patent to the effect that:—

"Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—"

This means that the applicant must state briefly and clearly what is the essence of the invention, which he has already described at some length. For example, in making a toning bath, it may be the use of a particular chemical or a special manner of mixing known chemicals. Many people, however, will think they require to say what advantages they claim for the invention, and we have heard of inexperienced patentees drawing up claims such as "that it is unique," that "there is nothing like it on the market," or even that "£10,000 is its value." A study of the published specifications of similar inventions, which have been brought into correspondence with the official form in their passage through the Patent Office, will give a good idea of the way in which the claims should be drafted.

Generally speaking, in reference to inventions of photographic apparatus and accessories such as may owe their origination to the ingenuity of individual professional or amateur photographers, we regard the taking out of a patent as a means of warning that the originator is alive to his rights in it. The taking out of a provisional patent at the cost of £1 is sufficient for this purpose. Although it does not permit of legal action being taken until the patent has been granted, nevertheless the inventor is in the position to protect himself from any unscrupulous pilfering of his idea by anyone to whom he may show it in confidence. On this account many of the manufacturing houses adopt the practice of declining the disclosure to them of an invention until the applicant has applied for patent protection. By so doing they acquit themselves of any suspicion of being anxious to benefit by the inventor's unprotected state. Unless an invention contains some really substantial commercial prospect it will usually not be to the inventor's interest to pursue his protection very far. After the completed specification has been accepted and the patent sealed, the patent rights may be disposed of to the firm which has offered to buy them, and the question of the further payment of taxes for the purpose of maintaining the patent in being may be left to the purchasing firm. Presuming that an inventor is content with a modest recompense for his ingenuity in the form of cash for his rights, there is no doubt that there is a constant demand for inventions of the hundred and one accessories for use in photography, the sale of which flourished in this country before the war, and will doubtless flourish again.

THE LONDON SALON OF PHOTOGRAPHY.

PORTRAITS AND FIGURE WORK.

WE cannot direct our readers to more than two or three things of remarkable power or novelty amongst the portraits shown at the annual exhibition in Pall Mall; but we promise that a visit to the show will be repaid by the interest nearly every print displays. The average of merit is a high one; a state of things which has now happily become usual in these shows. Perhaps this is because photographers are at last a little shy of surprises, as surprises, and are turning their attention to results that are artistic in the true sense of the term.

The outstanding exhibit, to our minds, is the collection of work shown by a professional photographer of Bath, Herbert Lambert, who sends half a dozen portraits that are really arresting on account of their technical merit, and the simple and straightforward methods they reveal. It might perhaps be admitted that they are conventional; but from a professional point of view that is no disadvantage if the work has "pull."

A mild sensation may exist in the fact that the Queen of Roumania's signature distinguishes her portrait shown by Bertram Park. Beyond this there is nothing needing exclamation marks in the work contributed by British professionals, which include Marcus Adams, Angus and Maud Basil, Charles Borup, Hugh Cecil, William Crooke, Mrs. Corke, A. Keith Dannatt, Miss Vandamm, C. Vandyke, H. Van Wadenoyen, and C. Zilva.

Taking a systematic tour of the galleries and breaking off here and there to follow up an exhibitor's work, we find first a spirited portrait of "The Rt. Hon. the Earl of Carnarvon" (1), by F. Seyton Scott. As a virile character-study this is very successful. It has the distinction of amateur work. We do not mean that it is amateurish, far from it; but it has the sly snapshot look which is totally at variance with the reposeful presentment that lies in the principle of professional work. We are disposed to believe that the momentary expression, sometimes animated to the degree of spoiling the normal likeness, which the amateur style chiefly involves, is less desirable than the monumental principle employed by traditional workers like Crooke. "Study of a Head" (14), by Marcus Adams, exhibits a tendency for over-modulated backgrounds in this gentleman's work. "Daddy's Sweetheart" (129) is a particularly sweet child, and the print seems to have been treated with a consistent sweetness that recalls a little the surface of a wax or china doll. Perhaps the nicest of these child studies is "Peter" (171), a profile, because it is the strongest, although "Betty" (174) is prettier. But for character Mr. Adams has done nothing better than "Mischief" (181), a girl in a print dress. "Simplicity" (182) completes the list of a series that must inevitably redound to the credit and profit of their author.

The evergreen dodge of placing a sitter in the dark against a veiled window has given Hugo Van Wadenoyen his "Silhouette" (17), which certainly offers a fine pattern. Fortunately he has provided sufficient reflected light to give interest to planes and details within the silhouette. In "Betty" (132) he avails himself of another stock-in-trade—namely, the shadow on the wall. He rises to his highest level of style, however, in "Lady with Striped Scarf" (148), the broad and simple treatment of which is imposing.

When N. E. Luboshez sent two epoch-making portraits last year to the R.P.S. show, we thought that portraiture by photography had found a leader to "go over the top" and take all the squad with him. But he has come back into the trench again, and we are all where we were. His work is marvellously strong, of course, but he has not been so happy in the selection made by the Salon as he was in the R.P.S.'s choice last year. "A Study in Lighting" (37) is the best of his prints. It is the

portrait of a gentleman the brim of whose hat shades his face below his eyes. The modelling is very strong and artistic, and the whole thing is Rembrandtesque in feeling and aim. If he had sent nothing else at all he would have done wisely. The other prints fall away from this and from his previously exhibited work. "Portrait" (165) is comparatively flat in materialisation, and the lighting is not consistent, nothing but the face receiving any illumination at all. "N. Tchaikowsky" (274) likewise wants roundness, and although really fine in a general way, is rather dull. "Study" (314) is a bearded head only of the sardine skipper variety. It has virility and power of handling.

Handwork is the chief feature of Jane Reece's profile of a boy in a large hat, entitled "In Spanish Vein" (38). We must confess that to us neither the youth nor his portrait appear more in the vein of Spain than of Holland or Mexico, or any other place. We may be wrong, but the only effect the wiry scratches on the background around the brim of the hat appear to have is to make the background envelop the head instead of remaining behind it. We much prefer Miss Reece's saner portrait "My Mother" (52), which, though rather too fuzzy for its small scale, has much quality and charm.

Angus Basil was out for contrast when he produced "Yvette" (45), the study of a pretty young girl with "bobbed" hair and bare legs, dressed with some brevity in a white garment, and standing against a black curtain. But the effect is striking and in perfect taste. There is admirable character in his "Liev Leonoff" (267). Maud Basil's "Sisters" (56) is a print which has attracted considerable attention on account of the strong effect afforded by the large field of beautiful middle tone, the dark note of the hair, and the brilliant halo effect where the back lighting shines through. We also confess to being charmed, but are disposed to think the scheme a specious one. The hair suggests the badger. But as to the quality in the half-tones there is no doubt whatever; neither is there any as to the happy posing of the two girls, one looking at the other, and the other looking at the spectator.

Walter Lee's "Yank" (50), a full face in the goggles which have already invaded these islands, is masterly in its way, but inexplicably low in tone. Two nice little boys form the subject of "The Brothers" (81), by George Spiers. This print has an effective treatment, embodying the rosy texture of background now popular.

Hugh Cecil's two portraits are similar in character, a "pair," in fact. They are "Margaret Morris" (79) and "Portrait" (89). Although posed with the skill for which this worker is famous, they appear to us to suffer from the treatment he has adopted in rendering their tones in flat areas bounded by rather hard edges. Even the bare shoulders of "Portrait" are not permitted that roundness and modelling which are, after all, the charm of shoulders.

"Miss Marjorie Hume" (91) is a portrait by the amateur, J. C. Warburg, but quite in the professional manner. It is extremely nice in its varied tones. Another amateur, the Rajah of Sarawak, sends a well-rendered vignette head of a native girl, something less than an absolute profile, in which the fine texture of the head-dress is really the most remarkable part of the achievement. It is called "Malay Girl, Sarawak" (106).

One of the most engaging portraits here is "Madeleine" (111), by Herbert Lambert. It is only surpassed by "Portrait" (204), a head and bust of great beauty. Madeleine is a print of a young girl, of charming simplicity. In style it is broad and masterly. The more mature lady of the "Portrait" is

rendered with less unconventionality; but its charm is no less irresistible. Mr. Lambert is content with what his negative gives him, and one could not, in his case, wish for any modifications. "Molly" (201) is a child whose hair has a stripey appearance which we are not quite sure that we admire. But a vignetted head, called "Profile" (207), shows a style of clean delicate tones, and a most artistic management of contours.

"Her Royal Highness Princess Ileana of Roumania" (127) is one of Bertram Park's distinguished sitters. He has given her much charm, in spite of a scheme of lighting which proclaims itself as undoubtedly artificial. As a matter of fact, the tone values are not at all what natural lighting would give, but it is plain that such matters are not considered in Dover Street. "Nevinson" (133) is a very clever study in a style of retouching by which Mr. Park has recalled the "cubistic" touch of the painter. Its merit lies in the fact that, although it is very demonstrative, it does not much damage the modelling. Next we have the other royalty, "Her Majesty the Queen of Roumania" (189), a first-rate work, having the distinction of style that is its due.

Waldemar Eide works in Norway. His "Stefan Partos" (134) is a beautiful little costume portrait of a young gentleman of saddened and serious mien. To us the portrait appears to be eminently fitted for a conception of what the Chevalier Grioux might have been. "Madame Vera Fokina" (266) maintains a dignified pose suitable for a Roman matron. In fact, this clever photographer is eminently strong in the picturesque characterisation of his sitters.

Wm. Crooke sends three examples, the best of which, by a long way, is "Sir Henry Wood" (188), for it is a strong conception of a virile subject. The lighting is forceful, and the expression is of that settled and serene kind which, though it demands repose of the facial muscles, does not relinquish the look of mental alertness. Mr. Crooke has turned the fur collar of the musician to good account. More conventional in style and pose is the upstanding figure of "The Right Hon. James Avon Clyde, K.C., M.P., Lord Advocate" (240)—all that, as the gentleman's bearing suggests. Perhaps, if the work is a presentation portrait, it is right that it should. The "Portrait of an Old Lady" (308) misses the full measure of quality that is usually found in Mr. Crooke's works.

A very dull, but uncommonly good character study of a stalwart gentleman, "Peter Cornelius" (209), seated and tranquil, comes from C. Zilva. The Earl of Carnarvon shows a good motive in design with the bending lines and inclined head of "Madame Karsavina" (214), a sad-looking young lady. Florence Vandamm contributes a small print, "Mica Micum" (230), a lady evidently of character. Here she rather appears to be suppressing some violent emotion. Compressed lips and distended nostrils may be characteristics, and may make for likeness, but we doubt the advantage of carrying these considerations beyond those of the more alluring charms of a sitter. Miss Vandamm's "G. R. Thomas" (348) is all that can be wished for in this respect, with its sober style and gentle lighting. The cigarette is a happy touch.

We have always looked to Louis Fleckenstein for work instinct with high artistic aim and feeling, and his present exhibits do not disappoint us. In "Betello Rubino" (258) we see again that large and simple style to which we have already referred in Mr. Lambert's "Madeleine." It gives to Mr. Fleckenstein's portrait the look of a drawing by an old master. In fact, the thought it brought to mind was that of one of Raphael's Madonnas; for the work has the same quiet and noble demureness. Similarly, we are reminded of Rembrandt in the tone and the style of "Miss Lucille S." (315). With pose dignified, and lighting simple and effective, this portrait sets a fine example for nobility of treatment.

There is something delightfully quaint in Ford Stirling's "Miss Chichester" (247) whose bent elbow seems to have been

the cause of the slim figure's one-sided position on the print. The clear, gentle tones and manner of lighting show a refined taste. We cannot say quite so much for Margrethe Mather's joke of getting spots of high light on the goggles of "Edward Weston" (259). "Magda A." (264) is another welcome example of the simple and broad style by Aage Remfeldt, who also has achieved a capital pose and a sweet expression in "Miss A. A. R." (304), which, however, is needlessly dark.

A portrait of much quality, though a little wooden in the neck and body, is Arthur F. Kales's "Miss Julianne Johnston" (269), a profile figure with full face, nicely lit. Otto C. Schulte, in his "Portrait of Miss B." (270), makes what is, in our mind, the mistake of putting the sitter so near the background as to muddle its contours against the cast shadow. In "Portrait of a Lady" (286), C. Vandyk shows us one of the excellent productions of his studio, but it calls for no special remark. Yvonne Park employs the resource of the bright edging of light through the texture of fur in her pretty "Girl's Head" (296).

Originality is the keynote of Dora Head's "Pals" (298). This is the head and shoulders of two laughing youths, one of whom has a pipe in his mouth. It is a capital piece of life and animation. Equally good in its way is Chas. F. Emery's "Disdain" (299), a splendidly strong presentation of a girl's head thrown back in what to us seems more like impertinent airs than disdain; but the expression is well given, however it be named. Another original and lively work comes from Chas. H. Davis, "Mr. Otis Skinner (in character)" (320). The figure stands with folded arms and a perky smile, and is, presumably, Micawber, to judge by his costume. Similar excellencies are in J. A. Gardner's "Old Yankee Farmer" (420), but here the character is genuine, not assumed. The wit and good nature in this face under its battered hat makes it a triumph.

"Eileen" (322), by Estelle, is a young girl seated, in profile, but looking round demurely at full face. The expression is delightfully childlike. Another nice demure pose is given by Charles Borup in "Phyllis and Crinoline" (338), quite a pretty picture. Character, happy expression, and pose, and an excellent, quiet style distinguish "E. Haynes, Esq." (339), by Nicholas E. Smirnoff. Henry B. Goodwin also shows a fine head stylishly treated in "His Excellency M. Thiébaud" (401)—a splendid portrait for ambassadorial purposes.

Our remarks so far have been all in praise; but we must record our disagreement with the aim of Grace S. Parrish, whose "Decorative Portrait" (432) seems to us nothing but a regrettable absurdity. Its "decoration" consists in its being all eliminated in a washed-out way, except for a few hard lines; whilst the background is scrawled with some very ill-drawn figures in outline.

Fortunately the Salon has not admitted much with which a sane mind can quarrel. Among the figure subjects that are not portraits pure and simple, some specially fine pictorial work is to be seen. We must refer to a few of the most striking.

The visitor will admire the Earl of Carnarvon's study (9) representing a lady in a shimmering robe. The face is delightful, and the pose most cleverly given a sort of list by the extension of the sitter's right arm under the drapery. A rather fleshly nude, posed with an abandon worthy of Titian, comes from Henry B. Goodwin. It is called "The Tired Model" (18). Our only criticism is that the modelling is faulty, a kind of mottling in the tone having upset all the delicacies of shading and prevented any idea of roundness. F. J. Mortimer's "Naiad" (30) is similarly unrealised, but it is a remarkably clever piece of picture-making. He has been faced with the problem of tone accents; the body of the girl, who stands back towards us at the sea's edge, contesting the high-lights of the breakers beyond. We think that sharper and darker touches of shadow in the figure would have effectively given her prominence; and it would have done so without robbing either her or

the waves of the high-lights. Waldemar Eide's "Idol" (64) is well posed, and the "make-up" of the eyes is wonderful. The "Swastikas" on the background should commend this design as a poster to the National War Savings Committee.

Never since an enterprising American years ago produced prints in the scrap-album manner have we seen so much "too solid flesh" in a single picture as in Francis Jay's "En Arcadie—Dessin pour Eventail" (84). It is really a cleverly composed scene of nearly a score of nude damsels disporting at a woodland stream; but as a design for a fan we fear it would be disastrous. The fan would be about fifteen inches long with about two inches of handle. Its lines are not arcs either. Mr. Jay should have called it a design for a "lunette." All such designs are for lunettes: no other decorated architectural space is ever provided for. It would be interesting to see (from a distance) the lady with moral courage enough to display this fan at a respectable social function.

A pretty picture is sent by T. O. Sheckell of a young girl daintily holding her skirts by her fingers, with sunlight behind her. He calls it "At Sweet Sixteen" (120). Another lighting study, and one of particular merit, is Ed. Weston's "Paul Jordan Smith" (152). This represents a young man leaning against a wall upon which a strong light falls from behind. In the midst of the cast shadow the photographer has introduced the further complexity of a mirror which reflects the head, whilst, of course, cutting out all the shadow by the light it also reflects.

We admire Angus Basil's "Mdlle. Dyta Morena" (173). It is a kneeling figure with arms outstretched. A shadow from the hands falls upon the face. Girls, with a certain liveliness, sitting on stools, form the subject both of F. J. Mortimer's "Chippy" (70), nicely designed but dark; and "On Dit" (197), by Andrew Barclay. F. Flodin attempts a portrait of "Sir Walter Raleigh" (206), which is by no means a bad fancy. We were disappointed to find that what we first took for a corn-cob pipe in his mouth was really only a rectangular shadow in his ruff. The idea of imaginary portraits is one that should supply resourceful amateurs with interesting objectives.

A curious flat print, full of anomalies in tone, has been sent under the name of "Sepulveda" (218), by Jose Ortiz Echague. It comprises two Spanish peasants who effectively resemble cut-out fire screens, since they have but two dimensions. The thing is inexplicable and not beautiful. Another queer picture is "Need" (223)—three ladies holding

each other up in what appears to be an attack of *mal de mer*. Photographically, however, it is first rate. J. Falkengren is responsible for its merits and defects. "When I sit alone and think" (233) is Mrs. Barton's title to another two-dimensional effort depicting a girl in a wood. It is flatter than the flattest primitive art, and looks like a piece of tapestry. We do not need to sit alone to think that Mrs. Barton would do wiser to recognise the existence of space and air. What a lifting of spirit one finds in turning to such a living, human piece of work as "Idle Moments" (238), by C. J. Marvin, who gives us a ducky boy sitting by a wall! The lighting and beauty of the tones in this picture are a joy. Light again is the burden of Louis Fleckenstein's song in a rocky view where a girl is gracefully posed. He calls it, in fact, "Play of Light" (263). In such directions as this there is illimitable promise of progress. To ape the incompetence of the past cannot be profitable in any respect. Mr. Fleckenstein is happy again in his "Elizabeth Kislbury" (385), where the subject is the illumination of the figure by reflected light.

Two splendid studies of Japanese actors, in all their wondrous "get-up" of mask and wig, are sent by C. P. Crowther. The characters are, we understand, participators in some national ritual dance, and the prints are called "A 'No' Performer" (268 and 283). Among R. Polak's several interesting costume pictures after the style of Dutch art is a weird thing: a head of a bearded man lying upon what might be a "charger." But the head can never be that of the Baptist; we presume it is meant for that of Holofernes. Mr. Polak simply calls it "Study of a Head" (349), which is rather a "let down."

Perhaps the best of the many dancing subjects here, to turn from grave to gay, is W. Eide's "Dancing Study" (428), a print of rare quality. The pose is positively new, exhibiting all the vigour of a figure balanced on one foot, but devoid of the ill grace sometimes characteristic of this kind of posing. The shimmer of a silvery garment around the figure is a splendid detail in the scheme.

There are a quantity of most engaging baby-studies here also, all good, but scarcely requiring separate mention.

We have, indeed, not dealt with everything that deserves praise. Several nude studies, for example, the excellent contributions of Mr. and Mrs. Bertram Park, will be spoken of at some length in Mr. Tilney's article to appear a week hence.

As a show of professional and amateur portraiture we are sure that the Salon will repay a visit from all whose desire it is to see how the world wags and glean valuable suggestions.

METHODS AND NOVELTIES IN ENLARGING.

[A recent talk by Mr. Frank B. Howe, before the Californian Camera Club, the text of which is published in "Camera Craft," concerned itself chiefly with some of the by-paths of enlarging, and thus dealt with a number of methods which are comparatively little known by users of the enlarging process. We reprint portions of Mr. Howe's talk. The parts omitted are those which cover more or less familiar ground.—Eds. "B.J."]

Those of you who, like myself, enjoy having a little place fixed up in the cellar or the garage, a place where you can splash around, spill hypo to your heart's content, and otherwise enjoy yourself without incurring the horrified and sarcastic displeasure of your immediate family, will be glad, I think, to know that it is possible to have an enlarging apparatus which does not require an arc light, a Cooper-Hewitt tube, or daylight. Neither is it necessary to cut a hole in the wall or block out a window in order that it may be installed. Briefly, the apparatus may be called a Mazda lamp enlarging illuminator. A box about eighteen inches square and eight or ten inches deep is built, leaving one of its large sides open, as, in use,

it stands on one of its narrow sides. Mirror glass is attached to the inner surface of the back and four sides of this box, completely lining it with reflecting surfaces. In the centre of the back a hole is cut to accommodate an ordinary electric light socket, and four other sockets are also fitted, two on each side, so that the four lamps, when screwed in, will have their ends about an inch from the central one. By using two pieces of mirror to line the back of the box the glass dealer has only to pinch out two semicircles, one in each half where the two come together down the centre, and so doing will be much less expensive than cutting a round hole in the centre of a piece large enough to cover the entire back. The same applies

to the sides. These large blue lamps, seventy-five watts I think they call them, are the best, and comparatively inexpensive. On the front of this box is built a framework, with cleats inside holding a sheet of ground-glass. If, later, one sheet is found to be not enough, more can be added. To the front of this last is added still another frame, one somewhat like a picture frame, with its inside opening just large enough to take the back of your camera snugly. That is all there is to the apparatus. You then simply put your camera in the opening, after having first removed the ground-glass focusing screen, slip the negative into a plateholder from which the septum or centre has been removed, and you are ready for business. In cutting away this septum, leave about one-eighth inch of the material for support around the edges. A film negative can, of course, be placed between two pieces of clear glass fitting the holder, while a smaller negative can be placed in a carrier or attached to a clear glass. If you are using a Kodak or other camera that is without a plate attachment, you can make the section carrying the ground-glass a little wider and cut a slit in one side so that the plateholder carrying the negative can be inserted there.

For enlarging, the speed of the lens is not as important as is flatness of field, and any lens which gives the latter will do. The ideal lens for enlarging has a focal length equal to the diagonal of the plate lens, so makers agree in telling us. You will understand that I am touching on this subject of lenses only briefly, because it is one that is covered in innumerable books and articles very much more interestingly and at greater length than I can hope to achieve. If your only available lens is a rapid rectilinear—and haven't we all, put away somewhere, whether we admit it or not, such a lens for which we have a secret fondness that we never will have for the finest anastigmat made?—if, as I say, you have only such a lens, do not think you cannot make good enlargements with it, for you can. But a good anastigmat is the better optical equipment; if you have one, it is the lens to use.

So much for the equipment. Let us get down to the actual making of the print. You doubtless have no trouble with straight enlarging, so we will proceed directly to the matter of exposing, with special consideration to so-called fancy printing. The soft-focus or mezzotint effect, which is the result of a diffused picture from a sharp negative, is easily achieved in enlarging. We first focus sharply, then rack out the lens until the image is slightly out of focus, place the paper in position, open the shutter, and give about one-fourth the exposure, after which the lens is drawn back into the sharp-focus position and the balance of the exposure given. Of course, the proportioning of the two exposures will vary with individual pictures; but one-fourth soft focus and three-fourths sharp seems best to fit the average case.

And, by the way, let me urge you to make, if you already haven't one, a transparent yellow cap for your lens. With it in position you can place the paper on the easel and focus right through the yellow screen without danger of fogging the paper, thereby seeing just how you are placing it on the paper. There are not a few advantages in using this screen. You can make one in a few minutes by taking a lens cap, cutting out the top and gluing a piece of orange Kodaloid over it. If you haven't any Kodaloid at hand, run a piece of undeveloped film through the hypo, wash it and soak it in red ink until it acquires the proper depth of colour.

Those wide-border, countersunk enlargements which have become popular of late under the names of Velvetone, Bruner-type, and the like, are easily made, and beautiful in effect. They are produced commercially on platino-matt paper, through a Verito lens; but, if you haven't a soft-focus lens,

you can get a like effect by making the exposure with a stretcher covered with silk bolting cloth moved around about half an inch in front of the paper while the exposure is being made. Leave four or five inches of white border around the picture and develop for a cold grey tone, using not too much bromide, nor, indeed, too little. Brown and green tones do not look well for this type of print. Let the image develop slowly, with good brilliancy, and, above all, be sure to so expose that it takes full development. Take the dry print, lay it over a sheet of glass with a light underneath, place a sheet of heavy celluloid, cut the right size for the desired "plate-

Etching Effect.

Gum-print Effect.

sunk" effect between, and rub down the outside margin, thus countersinking the picture. The celluloid, being transparent, facilitates the centring of the picture; and, for rubbing down, one of the ball bearing embossing tools is fine; but, if not available, you can get the same result by using an old tooth-brush handle. Then trim the print to get neat, clean edges, and you have a beautiful picture.

To make prints resembling an etching, make a positive from your negative, using a process plate. Reduce it, getting it pretty thin, and flow the back with ground-glass substitute.

From Original Negative.

Bas-relief Effect.

Then lay this over the negative, with a light below, and on the ground-glass surface sketch in the picture with pencil. Then make a negative from this and from this last you can make a straight enlargement which will have the etching effect. It sounds complicated, but try it, and you will find it is really very easy to do; and it gives a novel effect, one that is very pleasing.

A bas-relief effect can be very easily obtained in enlarging. Make a positive on a plate or film—commercial film is fine—getting it as near as you can to the same density and contrast as

the negative. Put the two together, face to face, keeping them slightly out of register; make a negative, slip it into your enlarging camera, and proceed as for an ordinary enlargement.
